The scientific program was held at the camp of Dr. Howard Beach, at 8:00 P.M. Dr. Paul C. Clark, assistant professor of clinical medicine, Syracuse University College of Medicine, presented a paper on "Penicillin." This paper was given under the auspices and direction of the Council Committee on Public Health and Education of the Medical Society of the State of New York. Dr. Arthur S. Broga showed motion pictures.

#### Monroe County

Dr. Isadore Hurwitz, Rochester physician, returned home on July 19 from an Army hospital in Denver after serving two years as a captain in the Army Medical Corps. He served for eight months in the South Pacific.

Dr. Hurwitz was hospitalized in this country last April as a result of a medical disability suffered overseas. He is resuming his medical practice in Rochester.\*

Penfield now has a resident physician, Dr. Ellsworth S. Deuel.\*

#### Nassau County

Dr. Eugene H. Coon, vice-president of the Nassau County Medical Society, called a special meeting for the purpose of discussing diagnosis, treatment, and care of poliomyelitis cases. The

meeting was held at the Meadowbrook Hospital, August 18, at 9:00 P.M.

The speakers were Dr. James E. Perkins, director of communicable diseases of the State Health Department; Dr. John F. Landon, instructor of pediatrics at the Willard Parker Hospital, College of Physicians and Surgeons; and Dr. O. Ho C. Hudson, of the Meadowbrook Hospital.\*

#### New York County

At its meeting on Tuesday, June 20, the New York Psychoanalytic Society and Institute elected the following officers: president, Leonard Blumgart, M.D.; vice-president, Sandor Lorand, M.D.; secretary, Henry A. Bunker, M.D.; and treasurer, Z. Rita Parker, M.D.

The New York Academy of Medicine has set up plans for a continuous noncommercial drug exhibit at its headquarters. The exhibit will be in charge of a physicians' committee on drug exhibits which will work with an advisory committee of drug manufacturers. Dr. Theodore G. Klumpp, president of Winthrop Chemical Company, Rensselaer, is a chairman of the advisory committee. A person will be in charge of the exhibit who will be able to answer questions and explain new drugs, and pamphlets and literature will be furnished, giving the research and clinical usage and describing the products.

Because of the extreme importance of exact diagnosis in tropical diseases, the New York City Department of Health has expanded its facilities in order to furnish every possible aid to practicing physicians and hospitals throughout the city. This service is being conducted in cooperation with the tropical disease staff of the DeLamar Institute of Public Health of Columbia University.

**Laboratory Service:** The Tropical Disease Laboratory located at the Washington Heights Health Center, 600 West 168th Street, is now on a full-time basis. Services offered by the laboratory include examination of blood, feces, urine, etc., for parasites and for reactions associated with the presence of parasitic and other tropical diseases, as well as intradermal tests for trichinosis, echinococcus disease, and brucellosis. Specimens may be sent to this laboratory from 9:00 A.M. to 4:30 P.M. daily. Reports will be forwarded to the referring physician.

**Diagnostic Service:** Patients may be sent to the clinic at the laboratory for examinations. Upon completion of these, a report including the diagnosis and suggestions for treatment will be forwarded to the referring physician.

**Consultation Service:** Whenever necessary, bedside consultations will be provided.

The laboratory staff includes a specially trained technician, expert in parasitology; in addition, a large group of the regular laboratory staff of the Department of Health have been trained for this type of work should the need arise. The Department has appointed an epidemiologist in tropical diseases, Dr. Howard B. Shookhoff, a Diplomate of the American Board of Internal Medicine and of the Conjoint Board of England in Tropical Medicine and Hygiene, as well as a Fellow of the Royal Society of Tropical Medicine and Hygiene. Dr.

# SULFANILAMIDE IN SOLUTION •SURBYL

Pioneered by  
STRASENBURGH  
Research

● Surbyl is a balanced combination of Sulfanilamide, Urea and Benzyl Alcohol in a Propylene Glycol base.

Surbyl has been found valuable in the treatment of otitis media, paronychia, varicose ulcers, infections of the hand or foot and as a dressing for wounds and abscesses.

Surbyl Solution is free from excess alkalinity. The pH is between 7.5 and 8.0 which is a desirable range for topical administration.

Available in pint and gallon quantities. Write for professional folder S-12.

Shookhoff has had field experience in Puerto Rico and in Colombia, South America.

Referring physicians should telephone the Tropical Disease Diagnostic Service at Wadsworth 7-6300, Extension 18, so that necessary instructions for obtaining specimens may be given or appointments made for consultation.

President Allen Wardwell of the Association of the Bar of New York City has appointed the following committee on Medical Jurisprudence for the year 1944-45: John Kirkland Clark, *chairman*; Rogers H. Bacon, Eli H. Bronstein, Lawrence Ebstein, Julius Hallheimer, Edward Holloway, Sidney Jarcho, James D. C. Murray, Abraham Schwartz, James W. Scott, and George H. Sibley.

Dr. Kenneth B. Turner has been named head of the Records Section of the Committee on Medical Research of the American Medical Association.

Direct affiliation of the Fourth Medical and Surgical divisions of Bellevue Hospital with the College of Medicine of New York University was announced on July 15 by Dr. Harry Woodburn Chase, chancellor of the university, and Edward M. Bernecker, Commissioner of Hospitals for New York City, in a joint statement.

According to the announcement, the affiliation will "offer further opportunities for clinical teaching in the College of Medicine in addition to the present teaching services in the third (New York University) division of the hospital."

"New York University greatly appreciates the long and generous co-operation of the city authorities with its medical school," Chancellor Chase said. "This is a significant step in forwarding the effectiveness of our work as well as that of the hospital."

Dr. Charles H. Nammack and Dr. Arthur S. McQuillen, directors of the fourth division, have been appointed to the faculty of medicine of the university.\*

#### Oneida County

Medical aims of the present and postwar period as visualized by Dr. Herbert H. Bauckus, Buffalo, president of the Medical Society of the State of New York, were stressed by him on July 11 at the quarterly meeting of the county society held in Utica.

Dr. Bauckus made a plea for greater cancer control, greater expenditure of funds for the care of the insane, and more money for the complete elimination of tuberculosis.

The importance of the care of the "indigent through sickness" was emphasized by Dr. Bauckus. He referred to those gainfully employed who, when illness attacked them, had insufficient financial reserve until the time of their reemployment. He said they should receive the same benefits of medical care as those whose reserve is sufficient.

He emphasized the great help the group or non-profit hospital and medical plans have accomplished and complimented the local plans. Dr. Bauckus also discussed the extreme importance of care for returning war veterans.\*

#### Onondaga County

Dr. Herman G. Weiskotten, of Syracuse, was

reappointed to the Public Health Council on July 25 by Governor Thomas E. Dewey. The term of office of Council members is six years.

Dr. Weiskotten has been a member of the Council since 1936. He is dean of the College of Medicine of Syracuse University and has had wide experience in public health as well as in medical education.

A three-week training institute in health teaching to assist school administrators and teachers in carrying out the program set forth in the new State syllabus was given at Syracuse University August 14 to September 2. The university's department of physical education cooperated with the State Education Department in presenting the course.

The institute was under the leadership of Dr. John H. Shaw, president of the New York State Council on Health Teaching and assistant professor of physical education at Syracuse University.

Members who participated in development of the new syllabus and who assisted Dr. Shaw were Miss May Barnard, representative of the State School Nurse Teachers' Association on the Regents' advisory council; Miss Mary Bowen, supervisor of health teaching in the department of education, Syracuse; Miss Florence C. O'Neill and Miss Mary Rappaport, health-teaching supervisors, State Education Department; Miss Frances Van Arsdale, director of health, Binghamton, Dr. John E. Burke, assistant superintendent of schools in Schenectady and representative of the State Association of School Physicians on the Regents' advisory council; Dr. Charles McNeely, representative of the State Dental Society on the council; Dr. O. W. H. Mitchell, Syracuse University, representative of the State Medical Society on the council, and Dr. James Perkins, director of the division of communicable diseases, State Department of Health.\*

#### Ontario County

Two faculty members, Dr. Nathan P. Sears and Dr. Francis R. Irving, of the Syracuse University College of Medicine, addressed the quarterly meeting of the county society held on July 24 at the Geneva Country Club. Dr. Sears spoke on the subject "Gynecology in General Practice" and Dr. Irving discussed "Caudal Anesthesia in Obstetrics." The latter talk was illustrated with moving pictures.

Dr. J. Wendell Howard, of East Bloomfield, county society president, conducted the meeting, which was followed by a dinner at 6:30 o'clock.\*

Middlesex paid tribute to Dr. F. M. Chaffee for his forty years of medical service, at a banquet held in the Town Hall on August 1.

The banquet was attended by men and boys, many of whom were delivered as babies by the guest of honor.

Dr. Chaffee began his practice in Middlesex in the horse-and-buggy days and has answered calls night and day ever since except for the period of his service in the United States Army during World War I.

It is estimated that he has delivered over 5,000 babies in that time.

The speaker at the banquet was the Rev. Samuel G. Houghton, D.D., who began his ministry in the same town and at the same time that Dr. Chaffee began the practice of medicine.\*

[Continued from page 2048]

After combining the work of school physician with his regular practice for the past thirty years, Dr. James S. Allen, Geneva physician, is giving up the latter for the full-time school job this fall.

Dr. Allen began his medical practice in Geneva in 1910. He was graduated from Syracuse University Medical School in 1908.

During the first World War Dr. Allen spent two years in the Army Medical Corps, with the rank of lieutenant colonel. The following year he taught preventive medicine at Cornell University under Dr. Haven Emerson of New York City. Dr. Allen is president of Geneva's Board of Health and has been active as a member of the Geneva General Hospital staff, as well as in medical associations and groups in Ontario County and the State.\*

#### Oswego County

Dr. Abraham Ruhbarger, who was interned in Italy until being freed by the Allies, is giving his services for the care of the refugees from occupied Europe quartered at the emergency shelter at Fort Ontario, Oswego.\*

#### Queens County

Dr. Howard W. Neail, Jamaica, former coroner's physician and an assistant medical examiner of New York City for thirty-four years, during which time he performed 12,000 postmortem examinations and testified as a physician-detective at many important murder trials, has retired from public service.

Dr. Neail was a member of the first class graduated from Jamaica High School. He studied medicine at George Washington University.

Some of the well-known cases on which he worked were the Snyder-Gray case, the Major Green case, and the Jamaica "tobacco-road" case.\*

#### Schenectady County

Lt. Comdr. Quenton Jones has been assigned to the Schenectady blood donor center as a Navy doctor, it has been announced by Richard P. Davis, chairman of the center. Commander Jones, who has been connected with centers in New York and Pittsburgh, succeeds Lt. (j.g.) John Flynn, who has been assigned to other duty.

Commander Jones, whose home is in Utica, spent ten months on a destroyer in the Atlantic and saw action with the marines in the Pacific.\*

#### Suffolk County

The county society and its woman's auxiliary met July 27 for dinner and separate business meetings in the Shoreham in Sayville.\*

. . .

The new assistant director of Newark State School is Dr. Jacob Cohen, who was appointed to the position August 1, it is announced by Dr. H. G. Hubbell, acting director.

Dr. Hubbell, who has for many years served as assistant director (superintendent), has been acting director since the death of Dr. E. A. Witzel on May 15.

Dr. Cohen is a native of Montreal, and received his education in Montreal High School and McGill University, from which he was graduated in 1925 with the degree of M.D. The same year he entered service in the New York Department of Mental Hygiene as medical intern at King's Park State Hospital.

He was appointed assistant physician at Central Islip State Hospital in 1930 and served there successively as senior assistant and acting clinical director.

The new assistant director is a member of the New York State and Suffolk County medical societies, the American Psychiatric Association, and is president of the Long Island Psychiatric Society. He has also been active in the Suffolk County Council of the Boy Scouts.\*

#### Warren County

Dr. Edwin B. Jenks, of Diamond Point, Lake George, has been appointed chief of the Emergency Medical Unit in the Town of Bolton by Mark C. Doyle, director of the Warren County Office of Civilian Protection.\*

#### Wayne County

The Wayne County Medical Society honored its president and three other "country doctors" who have been active in their profession for the past fifty years, at a dinner meeting held on August 8 at Newark Country Club.

The four were Dr. Ralph Sheldon, of Lyons, society president; Dr. Samuel Houston, of Wolcott, Dr. C. P. Jennings, of Macedon, and Dr. George D. Winchell, of Rose.\*

## Graduate Fortnight of Academy of Medicine to Be Held in October

The New York Academy of Medicine will present its seventeenth graduate fortnight, on "Infections and Their Treatment," from October 9 to 20.

**Evening Session—8:30 O'Clock**

**New York Academy of Medicine**

*Monday, October 9*

- I. Address of Welcome  
Arthur Freeborn Chace, President, the New York Academy of Medicine
- II. Scientific program
  1. The Ludwig Kast Lecture\*: The Mode of Action of Antibacterial Agents  
René J. Dubos, Rockefeller Institute
  2. Factors Which Influence the Choice of Antibacterial Agents  
Colin M. MacLeod, Professor of Bacteriology, New York University College of Medicine

*Tuesday, October 10*

1. Sulfonamides in the control of streptococcus infections  
Hugh J. Morgan, Brig. Gen., U.S.A.
2. Mass Sulfadiazine Prophylaxis of Respiratory Diseases in the U.S. Navy.  
Alvin F. Coburn, Comdr., MC-V(S), USNR

*Wednesday, October 11*

1. Rickettsial Infections in the Southwest Pacific Area  
Francis G. Blake, Sterling Professor of Medicine, Yale University School of Medicine
2. Infectious Hepatitis  
S. Bayne-Jones, Brig. Gen., U.S.A.

*Thursday, October 12*

1. Chemotherapy of Syphilis  
Joseph Earle Moore, Associate Professor of Medicine, Johns Hopkins University School of Medicine
2. Chemotherapy of Gonorrhea  
John F. Mahoney, Senior Surgeon, USPHS

*Friday, October 13*

1. Chemotherapy in Acute Upper Respiratory Infections  
Russel L. Cecil, Professor of Clinical Medicine, Cornell University College of Medicine
2. The Carpenter Lecture: Influenza—Methods of Study and Control  
Thomas Francis, Jr., Professor of Epidemiology, School of Public Health, University of Michigan

*Monday, October 16*

1. The Use of Penicillin in the Treatment of Pneumococcal Infections  
William S. Tillett, Professor of Medicine, New York University College of Medicine
2. Primary Atypical Pneumonia  
John H. Dingle, Director, Commission on Acute Respiratory Diseases, Board for Investigation of Epidemic Diseases, U.S.A.

*Tuesday, October 17*

1. The Treatment of Osteomyelitis  
J. Albert Key, Clinical Professor of Orthopaedic Surgery, Washington University School of Medicine, St. Louis
2. Treatment of Burns and War Wounds  
Lewis K. Ferguson, Capt., (MC), USNR
3. Discussion  
Philip D. Wilson, Surgeon-in-Chief, Hospital for Special Surgery

\* In memory of Dr. Ludwig Kast, who proposed the Graduate Fortnight.

*Wednesday, October 18*

1. Recent Developments in Sulfonamide Therapy  
Harrison F. Flippin, University of Pennsylvania
2. Use of the Immune Globulin Fraction of Human Plasma in Acute Infections.  
Charles A. Janeway, Assistant Professor of Pediatrics, Harvard Medical School

*Thursday, October 19*

1. The Reactions of Tissues Following Infection and Their Place in an Environmental Conception of the Nature of Disease  
Wiley D. Forbus, Professor of Pathology, Duke University
2. Brucellosis (Undulant Fever)—Problems of Diagnosis and Treatment  
Harold J. Harris, Lt. Comdr., (MC), USNR

*Friday, October 20*

Panel Discussion: Evaluation of Sulfa Drugs and Penicillin

David P. Barr, *Chairman*; René J. Dubos, Colin M. MacLeod, John F. Mahoney, Frank L. Meleney, William S. Tillett

### Morning Panel Discussions

*Morning Panel Discussions will be held at the Academy as shown in the following schedule. Fellows of the Academy and registrants are invited to attend and participate. It is requested that questions for discussion be submitted in advance of the conference to Dr. Mahlon Ashford at the Academy, or if this is not feasible, they may be submitted in writing to the Chairman during the discussion.*

*Tuesday, October 10, 11:00—12:30 A.M.*

*Subject:* Pneumonia types and their response to various forms of chemotherapy

*Chairman:* Russell L. Cecil. *Members:* Alvan L. Barach; Maxwell Finland, Boston; Norman Plummer, Maj., (MC), AUS

*Friday, October 13, 11:00—12:30 A.M.*

*Subject:* Treatment of syphilis and gonorrhea

*Chairman:* Joseph Earle Moore, Baltimore. *Members:* Oscar F. Cox, Boston; Harry Eagle, Baltimore; Evan W. Thomas

*Tuesday, October 17, 11:00—12:30 A.M.*

*Subject:* Treatment of infections of eye, ear and upper respiratory tract

*Chairman:* Samuel J. Kopetzky. *Members:* Conrad Berens; C. Ward Crampton; W. Morgan Hartshorn; Westley M. Hunt; Charles J. Imperatori; John D. Kernan; Andrew B. Paul

### Afternoon Hospital Clinics

*Hospital Clinics will be held from 2:00 to 5:00 P.M. during the Fortnight. These clinics will be devoted to the course and treatment of infections.*

Tuesday, October 10—Bellevue and Beth Israel  
Wednesday, October 11—Babies and Montefiore  
Thursday, October 12—Morrisania and Mount Sinai

Friday, October 13—Home for Aged and Infirmary  
Hebrews and Post-Graduate

Monday, October 16—Lenox Hill and Woman's  
Tuesday, October 17—St. Luke's and Willard Parker

Wednesday, October 18—Jewish Hospital of Brooklyn and Presbyterian

Thursday, October 19—Flower-Fifth Avenue and New York

Friday, October 20—Polyclinic and Roosevelt

# Accent on Velvet Smoothness

The process used in manufacturing the "RAMSES"\* Flexible Cushioned Diaphragm produces a dome which is soft and pliable and can best be described as being as smooth as velvet.

This velvet-smoothness lessens the possibility of irritation during use.

The "RAMSES" Flexible Cushioned Diaphragm is manufactured in sizes of 50 to 95 millimeters in gradations of 5 millimeters. It is available on the order or prescription of the physician through any recognized pharmacy.

## Preliminary Plans for A.H.A. Meeting Announced

**P**RELIMINARY plans for the convention of the American Hospital Association to be held in Cleveland October 2 to 6 put the spotlight of attention on postwar planning, public health, rural hospital planning, trustees, and public relations. All are subjects for general sessions with no conflicting meetings.

The day-by-day program is as follows: Monday afternoon, postwar planning session; Monday night, president's session; Tuesday morning, public health session; Tuesday afternoon, sections on small hospitals, volunteers, purchasing, public hospitals, medical social service, and children's hospitals; Tuesday night, trustee session.

On Wednesday morning the rural hospital planning session is scheduled; Wednesday afternoon will include sections on Blue Cross plans, nursing, outpatient departments, business management, pharmacy, and tuberculosis; Wednesday evening will be the United Nations session.

Thursday morning is devoted to public relations. Sections on Thursday afternoon are: dietetic, records librarians, construction and mechanics, medi-

cal staff, personnel management, and mental hygiene.

The usual dinner and dance will take place in the evening. Friday morning is the "Mac and Bob" round table.

Among the speakers whose acceptances have been received are Thomas S. Gates, chairman of the Commission on Hospital Care and president of the University of Pennsylvania; Marshall E. Dimock, former assistant deputy administrator of the War Shipping Administration; Herluf V. Olsen, dean of Amos Tuck School of Business Administration, Dartmouth College; Morris Fishbein, M.D., editor, *J.A.M.A.*; Julius L. Wilson, M.D., president, American Trudeau Society; Robert Bingham, chairman of the board, Cleveland Hospital Council, and president, St. Luke's Hospital, Cleveland; John F. Hunt, of Foote, Cone, and Belding; Gladys Talbot Edwards, director of education, Farmers Educational and Cooperative Union of America; and Ellen Anderson, director of health education, Farm Foundation.—*The Modern Hospital*, August, 1944

## Dr. Bachmeyer Heads Hospitals' Survey

**D**R. ARTHUR C. BACHMEYER, of the University of Chicago, was appointed director of a two-year study of the country's hospital facilities and postwar hospital requirements at an organizational meeting of the Commission on Hospital Care held in Philadelphia in August.

Dr. Thomas S. Gates, president of the University of Pennsylvania, is chairman of the group of economic leaders and hospital authorities who com-

pose the commission, which recently was formed at the suggestion of the American Hospital Association.

Associate dean of the division of biologic sciences and director of hospitals at the University of Chicago, Dr. Bachmeyer will be in full charge of the study, which is designed to uncover the country's most pressing needs in hospital facilities and to make plans for meeting these requirements.

## REVIEWED

**Clinics.** Vol. II. February, 1944. No. 5. Edited by George Morris Piersol, M.D. Octavo of 226 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1944. Published bi-monthly. Paper, \$12, by subscription, \$2.00 a single copy. Cloth, \$16 by subscription, \$3.00 a single copy.

This issue of *Clinics* includes a symposium on war medicine which is timely and which should be of interest to the general practitioner as well as to the doctor engaged in military medicine. It is made up of teaching panels presented at the fifty-first annual meeting of the Association of Military Surgeons of the United States.

There is an especially illuminating discussion of chemotherapy, including pharmacology, toxicology, application, and results of the sulfonamides, penicillin, gramicidin, and antibiotic action on gram-positive and gram-negative bacilli.

The discussion of venereal diseases features such problems of control as diagnosis, treatment, epidemiology, prophylaxis, and education, which have arisen from the intensified large-scale activities accompanying warfare.

The importance of nutritional elements and their activity in combating fatigue are stressed.

Other enlightening discussions on fractures, plastic and reconstructive surgery, war wounds and burns, and gastrointestinal disorders, presented by men well versed in their subjects, make this volume worthy reading matter.

[Continued from page 2056]

The author has presented in a relatively compact volume a fairly comprehensive dissertation on biochemistry and the physiology of metabolism. It is not a textbook on the subject, nor is it intended to be one. It is planned for the medical and dental student.

The first part of the book is devoted to elementary physical chemistry and to the biochemistry of carbohydrates, proteins, and fats. The second part is devoted to the metabolism of foodstuffs. The author has included, in Part Three, a discussion of the energy requirements of the body, principles of nutrition, and the nature and composition of the common foodstuffs.

The book is well written.

WILLIAM S. COLLENS

The Medical Clinics of North America. Philadelphia Number. November, 1943. Index 1941-1943. Octavo. Philadelphia, W. B. Saunders Co., 1943. Published bimonthly (six numbers a year). Cloth, \$16 net; paper, \$12 net.

The Philadelphia Number of the *Medical Clinics of North America* is devoted mainly to a symposium on medical emergencies on the home front. There are several extremely interesting articles, of which those by Dr. Flippen *et al.* on sulfamerazine and by Dr. Reynold S. Griffith on recognition and management of cardiac emergencies are particularly good. Dr. Weiss' article on the psychosomatic aspects of medical practice in wartime will be of interest to everyone. In one article, by Dr. Frederick K. Albrecht, the use of amphetamine sulfate is recommended in the prevention and treatment of seasickness.

MILTON PLOTZ

Physical Foundations of Radiology. By Otto Glasser, Ph.D., Edith H. Quimby, Sc.D., Lauriston S. Taylor, Ph.D., and J. L. Weatherwax, M.A. Duodecimo of 426 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$5.00.

Four well-known physicists have pooled their experiences in radiologic physics and have produced a book most useful for the physician who wishes to become a specialist in radiology and for the radiologist who wishes to refresh and broaden his knowledge of physics.

From the physical aspects of the darkroom procedures all the way to the physical problems connected with dosage in x-ray and radium therapy, the reader will find every physical question answered authentically, clearly, concisely, and in a nonmathematical way.

The necessity for adequate protection is stressed with commendable emphasis. The results of genetic research have received due consideration with regard to protection.

The latest achievements of physics in general have been touched upon, and descriptive material of nuclear physics forms a welcome addition to the purely radiologic parts of the book.

S. W. WESTING

Know Your Hay Fever. By A. P. Sperling. With chapters on "Clinical Applications" by Arthur B. Berresford, M.D. Octavo of 241 pages, illustrated. New York, Frederick Fell, Inc., 1943. Cloth, \$2.00.

Without belittling the intelligence of the reader, the author has given a lucid explanation of hay fever, its symptoms, cause, effect, and treatment, that will be thoroughly understandable to the average layman.

His medical information is accurate and well documented. Evaluation of the various methods of

commend to your patients

Octavo of 104 pages Easton, Pa., Mack Printing Co., 1944 Paper

In 1  
Conv

1940, would be published in bound form as the need arose, the First Bound Supplement becomes official from July 1, 1944.

The Supplement contains thirty-four articles which have been added to the USP XII. Several articles refer to the same drug put up in different forms, for instance, diethylstilbestrol in powder form, in capsule, in tablet, and for injection. Among the other preparations may be mentioned hexavitamin, totaquine, triasyn B, triasyn B with liver, estradiol, liver B-vitamins injection, ergonovine maleate injection, menadione sodium bisulfite injection, dried yeast, sulfadiazine, sodium sulfadiazine, sulfaguanidine, sodium sulfithiazole, succinylsulfathiazole, stronger solution of hydrogen peroxide, oxophenarsine hydrochloride, and medicinal zinc peroxide

CHARLES SOLOMON

Small Community Hospitals. By Henry J. Southmayd and Geddes Smith. Octavo of 182 pages New York, Commonwealth Fund, 1944 Cloth, \$2.00

Of the many valuable projects undertaken by the Commonwealth Fund in the field of community health and medicine, the effort to extend the influence and effectiveness of the rural hospital is outstanding

This small volume presents, in compact form, the results of experience in the various phases of rural hospital administration. The chapter on "The Rural Hospital and the Medical Team" is of special interest to the clinical physician. The charts and tables in the appendix are very practical and should be equally interesting to him

ALFRED E. SHIPLEY

Education and Health of the Partially Seeing Child. By Winifred Hathaway. Octavo of 216 pages, illustrated. Published for the National Society for the Prevention of Blindness, Inc., by Columbia University Press, New York, 1943 \$2.50

This work, published for the National Society for the Prevention of Blindness, Inc., should be an excellent guide for the use of "administrators, supervisors, teachers, nurses, social workers and others concerned with the welfare of children" who are visually handicapped

It discusses the problems of finding the partially seeing children; the selection and preparation of the teacher, preparing the school, the equipment of classrooms, methods of conducting classes, and other kindred problems. This is also a chapter on "Facts about the Eye and Eye Hygiene" written in a simple and not too technical style for the non-medical worker.

STITT-STRONG

## Diagnosis, Prevention and Treatment of Tropical Diseases

6th Edition

By Richard P. Strong, M.D., D.S.M., C.B.

*Emeritus Professor of Tropical Medicine,  
Harvard University*

This is a work of timely interest to practitioners because of the very important studies the authors have made in recent tropical medicine and their firsthand knowledge of the latest developments around the world. The information presented is practical. The facts needed for making a correct diagnosis of any tropical disease, the clinical manifestations and treatment are fully presented. The zoological aspects and laboratory methods of importance in a study of transmission and prevention are also included. Consideration is given the important cosmopolitan diseases that may be encountered in warm countries and special attention is given to public health problems relating to prevention of infectious diseases and to diseases of tropical origin that may become endemic in temperate climates.

*Southern Medicine and Surgery*, says "The revision of this masterpiece comes at a particularly opportune time, when, by reason of the wider diffusion of tropical diseases by airplane travel and of the great number of fighting men in tropical countries, there is vital need to have intimate knowledge of these diseases, their prevention and cure."

*Archives of Dermatology and Syphilology*, says "It is a monumental work which reflects the greatest credit on the author and his associates."

## RAGWEED POLLEN COUNT STATIONS

For the first time since the Department started its ragweed pollen count surveys in 1937, stations will be located in the Catskill Mountain and Ulster as well as in the purpose is to determine whether or not hay fever havens can be established in that section of the State.

One of the stations has been installed on the farm of Justice C. C. VanValin. This farm is located in the north-central part of the Catskills in Greene County. The second station has been placed at Budapest Rest at Big Indian in the southern section of the Catskills in Ulster County.

Three stations will be operated this year in the Central Adirondacks: at Remsen, Oneida County, on the southern outskirts of the so-called pollen-free area; at Lowville, Lewis County, on the western rim of that area; and at North Creek, Warren County, on the northeastern edge of the "free" section. The purpose of installing stations in these three places is to ascertain whether the free area has enlarged as the result of continued effort to eliminate the weed over a period of years.

It is generally believed that some sections of the Catskills might be free from the pollen because of a

Stations, which were placed in operation on August 12, will continue through October 12 — *Health News*

## DRIVE FOR INDUSTRIAL NURSES

The American Association of Industrial Nurses will, on October 1, launch its drive for new members. This association was organized in 1942 in recognition of the growth and expansion of industrial nursing.

Though the war has brought an extraordinary growth in this area, some of which will be cut as war industries close, industrial nursing is now established as an important and permanent branch of nursing. It demands an organization whose policies are shaped by those who have blazed the trails in this area, and is enriched by the experiences of the new recruits.

Industrial nursing is an integral part of the growing movement to provide safety and health to our great worker population. This movement is a substantial and growing phase in our country's efforts to prevent accident and disease and to promote health.

The A.A.I.N. represents nurses in every field of industrial and mercantile establishments. Its governing board is representative of the country as a whole. Its membership requirements are on a par with those of other standard-making nursing bodies. The A.A.I.N. actively encourages membership in the nursing profession's official bodies, the district, state, and national nurses associations. It also

**NAVITOL  
WITH VIOSTEROL**

Three drops, an average daily prophylactic dose, supply:  
1,000 U.S.P. units Vitamin D • • • 5,000 U.S.P. units Vitamin A

Navitol with Viosterol is a highly potent source of the fat-soluble vitamins A and D. Because of its high potency, three drops supply an average prophylactic dose of both these vitamins which expectant mothers, infants, and children need.

Navitol with Viosterol is also economical. It places no strain

on the family budget because this daily three drop dose costs only about one-half cent, when the 50 cc bottle is used.

Navitol with Viosterol conforms to the maximum Vitamin A and D potencies of the U.S.P. XII preparation termed "Concentrated Oleo-vitamin A and D."

\* Navitol (Reg. U.S. Pat. Off.) is a trade mark of E. R. Squibb & Sons.

Contains per gram { 65,000 units of vitamin A  
13,000 units of vitamin D  
Supplied in 10 and 50 cc bottles with dropper.

THREEFOLD ACTION for Effective Relief of SPASM

## PAVATRINE *with* PHENOBARBITAL

Pavatrine—product of original Searle Research—already has established itself as an effective, non narcotic antispasmodic having a dual effect

- 1 **MUSCULOTROPIC**—local action upon smooth muscle
  - 2 **NEUROTROPIC**—through nerve supply to involuntary muscle.
- Now, for those patients showing nervous system irritability, an additional effect has been added
- 3 **MILD SEDATION**—by means of the non depressant, phenobarbital

Pavatrine with Phenobarbital provides effective symptomatic relief from gastrointestinal spasm (the irritable bowel), in the uterine hypertonicity of dysmenorrhea, and in spasticity of the urinary bladder

Each sugar coated tablet contains 125 mg (2 gr) Pavatrine (Searle) with 15 mg (¼ gr) Phenobarbital. Supplied in bottles of 100 and 1000

# THESODATE *Brewer*

(the original enteric-coated tablet of Theobromine Sodium Acetate)

*for*

CLINICALLY EFFECTIVE  
LOW TOXICITY  
EFFECTIVELY ENTERIC COATED

## CORONARY ARTERY DISEASE AND EDEMA

/ Medical authorities in journals and books have substantiated the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal Diseases. Actual clinical use has proven the usefulness of Thesodate (*Brewer*).

The enteric coating of Thesodate tablets permits adequate dosage, so necessary for best results with xanthines, for as prolonged a period of time as necessary.

Supplied with or without Phenobarbital, also with Potassium Iodide and Phenobarbital, in potencies for controllable dosage.

*Samples and literature on request.*

**BREWER & COMPANY, INC.**, Worcester  
*Massachusetts*

# MARINOL

## IMPROVED FORMULA

**MARINOL (IMPROVED FORMULA)** is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D<sub>3</sub>.

### OUTSTANDING PROPERTIES

**PALATABILITY:** The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

**HOMOGENIZATION:** This assures a uniform and stable product that permits of easy miscibility with milk, special formulac, fruit or vegetable juices, or with water.

**HIGH VITAMIN POTENCY:** 5,000 U.S.P. units of vitamin A and 500 U.S.P. units of Vitamin D<sub>3</sub> supply the daily minimum requirements

(FDA) in one teaspoonful.

**LOW COST:** A single teaspoonful daily is a prophylactic dose.

**FOOD VALUE:** Fish liver and vegetable oils supply another desirable property—that of caloric value.

**EASY ADMINISTRATION** is possible because of unusual potency of small dose.

**CONSUMER PRICE:** Bottle of 6 fl. oz. 85 cents. Bottle of 12 fl. oz. \$1.50 (M.P.R. 392). **HOW SUPPLIED** Bottles of 6 fl. oz. and 12 fl. oz.

## IN MILK DIETS

**W**hether human or cow's milk constitutes the basis of the average diet of early infancy, a deficiency of certain vitamin B factors can be looked upon as a natural corollary.<sup>1,2</sup>

White's Multi-Beta Liquid is specifically formulated to reinforce such diets—supplying the major B factors, in drop dosage, in amounts proportionate to average dietary insufficiency. Routine administration of five drops or more daily assures the infant an optimal supply of all clinically important B vitamins.

White's Multi-Beta Liquid is also a sound and economical supplement to such restricted adult diets as the Sippy and Karell regimes, or others based on milk diet. It is of value, too, when difficulty in swallowing tablets or capsules is encountered or when tube feeding is necessary.

1. Marriott, William McKim. "Infant Nutrition," revised by Jeans, Mosby, St. Louis, 3rd Edition, 1941
2. Jeans, Philip C.: "The Feeding of Healthy Infants and Children," J.A.M.A., 120.913, 1942.

*White's*

## MULTI-BETA LIQUID

Non-alcoholic. Ethically promoted. In bottles (with suitable droppers) of 10 cc., 25 cc., 50 cc. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

*White's* PRESCRIPTION *vitamins*

**It fights infection  
while she sleeps**

The striking success of Paredrine-Sulfathiazole Suspension in nasal and sinus infections is largely due to its prolonged bacteriostatic action. When the Suspension is administered on retiring, for example, sulfathiazole can often be observed on infected mucosa the next morning—conclusive evidence that bacteriostasis has persisted all night long.

The fundamental reason for this prolonged bacteriostatic action is the fact that Paredrine-Sulfathiazole Suspension—not a solution, but a *suspension* of free sulfathiazole—covers the nasal mucosa with a fine, even frosting of sulfathiazole, which does not quickly wash away. Yet the Suspension does not cake or clump, and does not interfere with normal ciliary action.

Other outstanding advantages:

1. The Suspension does not irritate or sting, because its pH is slightly acid, and identical with that of normal nasal secretions.
2. The Suspension does not produce such central nervous side effects as insomnia, restlessness and nervousness.

Smith, Kline & French Laboratories, Philadelphia, Pa.

## PAREDRIINE-SULFATHIAZOLE SUSPENSION

1 *Prolonged*  
bacteriostasis

2 *Non-stimulating*  
vasoconstriction

3 *Therapeutic*  
pH—5.5 to 6.5

## M<sup>Measuring results in arthritis therapy</sup>

Weight gain in a previously anorectic patient with arthritis is one of the measurable results in Ertron therapy.

This is a systemic response to treatment which cannot be accomplished with analgesic medication.

Such objective evidence as weight gain, increased muscular strength as measured by the grip dynamometer, diminished joint size, and cinematographically recorded increase in motion is thoroughly in accord with present standards of success in the treatment of arthritis.

The Ertronized patient *feels* better and *is* better.

# ERTRON

## ERTRONIZE THE ARTHRITIC

**ERTRONIZE MEANS.** Employ Ertron in adequate dosage over a sufficiently long period to produce beneficial results. Gradually increase the dosage to that recommended or to the toleration level. Maintain this dosage until maximum improvement occurs.

**ERTRON\*** alone—and no other product—contains electrically activated, vaporized ergosterol (Whittier Process).

Supplied in bottles of 50, 100 and 500 capsules.

**ETHICALLY PROMOTED**

**NUTRITION RESEARCH LABORATORIES**  
CHICAGO

### ERTRON Parenteral

For the physician who wishes to supplement the routine oral administration of Ertron by parenteral injections, Ertron Parenteral is available in packages of six 1cc. ampules. Each ampule contains 500,000 U.S.P. units of electrically activated, vaporized ergosterol (Whittier Process).

# NOW AVAILABLE (without priorities) FOR CIVILIAN HOSPITALS

In hospitals of the armed forces and by virtue of nearly 150 foreign-body operations performed in leading civilian hospitals\* during the last two years, the Berman Metal Locator (now available to civilian hospitals) has been found to be "as indispensable as x-ray." The Locator is used both pre-operatively and at the operating table serving to reorient the foreign body accurately during the progress of the operation regardless of any shifting or movement within the tissue. The Locator now available with SOUND in addition to indicating dial.

Clinical experience with the Locator has shown:

1. Failure is practically unknown.
2. Removal time reduced in most cases to a matter of minutes.
3. Trauma greatly minimized.

Described in Journal of A.M.A., Jan. 9, 1943, vol. 121, pp. 123-125;  
Amer. Journal of Surgery, Sept. 1944, vol. LXV, no. 3, pp. 373-380;  
Archives of Ophthalmology, Mar. 1944, vol. 31, pp. 207-210.

## Indispensable as x-ray

Write for booklet illustrated with x-ray photographs, describing the Berman Metal Locator; prices and delivery dates.

*\*Performed with the aid of Locator and operator lent to the hospitals by Waugh Laboratories.*

**NOT ONLY CONTRA-INFECTIVE**—There are important properties in addition to bacteriostasis which make ARGYROL the "Physiologic Antiseptic"—one which works in harmony with the normal defense functions of tissues, nerves, cilia and circulatory system. Of first importance is the fact that ARGYROL is both antiseptic and decongestive.

**NOT ONLY CONTRA-CONGESTIVE**—There is an EXTRA FACTOR in mucous membrane antiseptics, in decongestion with ARGYROL. This important factor is physiologic stimulation of tissue defense function. It is a combination of physico chemical and bacteriostatic properties which go far beyond the usual concept of what an antiseptic should do. For:

**ARGYROL IS DETERGENT • PROTECTIVE • PUS-DISLODGING • INFLAMMATION-DISPELLING • SOOTHING • STIMULATING TO GLANDS, TISSUES.**

MADE ONLY BY THE A. C. BARNES COMPANY

NEW BRUNSWICK, N. J.

OF TISSUE DEFENSE FUNCTION

# IN IMPAIRED FAT DIGESTION

Degalol, the original chemically pure deoxycholic acid, is the constituent of human bile which is chiefly concerned with the emulsification of ingested fats.

When bile secretion is deficient, or totally lacking as in biliary fistula, the administration of Degalol assures not only digestion and

absorption of food fats but also of the fat-soluble vitamins A, D, E, and K.

When fatty foods prove intolerable in the absence of cholecystic pathology, Degalol usually relieves the postprandial distress and permits of liberalization of the diet.

Supplied in boxes of 100 1½ grain tablets.

Riedel - de Haen, Inc., New York 13, N. Y.

## IN WHOOPING COUGH

### ELIXIR BROMAURATE IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of the illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

GOLD PHARMACAL Co., New York -

# The ideal answer to wound infection IS ITS PREVENTION

**I**T is axiomatic that virtually all wounds are contaminated and thus susceptible to infection.

Since the presence of infection retards wound healing, its prevention is a powerful factor favoring healing.

Azochloramid\* is a valuable and widely used germicide for prophylaxis against wound infections. It is effective against many types of pathogenic organisms ▲ active for prolonged periods even in the presence of organic matter ▲ virtually harmless to tissue.

Azochloramid requires a minimum of medical attention and dressing changes. It is a convenient and economical means of combatting infection in most types of contaminated lesions.

# The Combination Packages of

W. B. E. Smith Bros. & Co. (Hynson, who usual concentration (5000 Oxford units per cc.) inject 20 cc. of physiologic salt solution into the vial in the usual aseptic procedure.

Invert the vial and syringe (with needle in vial), and withdraw the amount of penicillin solution required for the first injection.

Store vial with remainder of solution in refrigerator. Solution is ready for subsequent injections during the next 24 hours.

# PENICILLIN-C.S.C.

For administration in the physician's office or in the patient's home, Penicillin-C.S.C. will be available in a convenient combination package, as soon as the drug is released for unrestricted use in civilian practice. This combination package provides two rubber stoppered, serum type vials. One vial contains enough physiologic salt solution to permit the withdrawal of 20 cubic centimeters. The other vial contains 100,000 Oxford Units of penicillin sodium or penicillin calcium\* respectively.

The physiologic salt solution is sterile and free from fever-producing pyrogens. Penicillin-C.S.C.—whether the sodium salt or the calcium salt—is bacteriologically and biologically assayed to be of stated potency, sterile, and free from all toxic substances, including pyrogens, as attested by the control number on the package.

When 20 cc of the physiologic salt solution is withdrawn from its vial, and injected into the penicillin-containing vial under the usual aseptic precautions, the resultant solution presents a concentration of 5000 Oxford Units per cubic centimeter. The solution is then ready for injection, does not require resterilization.

After the desired amount of the solution for the first injection has been withdrawn, the vial containing the remainder of the solution should be stored in the refrigerator. It is ready for the next injection—the desired amount then merely has to be withdrawn under proper sterile technique.

When released for unrestricted marketing, Penicillin-C.S.C. will be stocked throughout the United States by a large number of selected wholesalers. Any pharmacist thus will be able to fill professional orders promptly.

# *Smoother Relief*

## in HEARTBURN and NAUSEA of PREGNANCY

In the light of modern evidence, the heartburn of pregnancy derives—not from a gastric hyperchlorhydria—but rather from a spasm of the cardiac sphincter of the esophagus.\*

Along with nausea of pregnancy, it is thus classified as essentially a neuromuscular disorder, calling for effective spasmolytic therapy.

Donnatal—a compound of phenobarbital with predetermined and controlled proportions of the belladonna alkaloids—proves particularly helpful in these often difficult cases, since it—

Affords all the advantages of natural belladonna alkaloids—  
**YET IS SIGNIFICANTLY NON-TOXIC;**

Provides for the sedation so frequently required—  
**YET IS ENTIRELY NON-NARCOTIC; AND**

Has marked pharmacologic potency—  
**YET COSTS LESS**

It actually costs about half as much as synthetic preparations—even less than tincture of belladonna and elixir of phenobarbital!

Formula: Each tablet contains belladonna alkaloids (hyoscyamine, atropine, and scopolamine) equivalent to approximately 5 min. tr. belladonna; plus 1/4 gr. phenobarbital.

Available: in bottles of 100 tablets.

## IN MASSIVE DOSAGE FOR CUTANEOUS AFFECTIONS

Whether the beneficial results obtained with Apolarthron in certain skin affections are due to a direct pharmacodynamic action or merely to the correction of a vitamin deficiency and its cutaneous manifestations, is yet to be determined. The fact remains that its administration in adequate dosage (3 to 4 capsules daily) rapidly produces notable results in acne, psoriasis and keratosis follicularis (Darier's disease).

A rapidly growing bibliography attests to the efficacy of both vitamins A and D in high potency, as found in Apolarthron, for the effective treatment of these skin diseases.

# APOLARTHRON

# *Smoother Relief*

## in HEARTBURN and NAUSEA of PREGNANCY

In the light of modern evidence, the heartburn of pregnancy derives—not from a gastric hyperchlorhydria—but rather from a spasm of the cardiac sphincter of the esophagus.\*

Along with nausea of pregnancy, it is thus classified as essentially a neuromuscular disorder, calling for effective spasmolytic therapy.

Donnatal—a compound of phenobarbital with predetermined and controlled proportions of the belladonna alkaloids—proves particularly helpful in these often difficult cases, since it—

1

*Affords all the advantages of natural belladonna alkaloids—*

**YET IS SIGNIFICANTLY NON-TOXIC;**

2

*Provides for the sedation so frequently required—*

**YET IS ENTIRELY NON-NARCOTIC; AND**

3

*Has marked pharmacologic potency—*

**YET COSTS LESS**

It actually costs about half as much as synthetic preparations—even less than tincture of belladonna and elixir of phenobarbital!

Formula: Each tablet contains belladonna alkaloids (hyoscyamine, atropine, and scopolamine) equivalent to approximately 5 min. tr. belladonna; plus ¼ gr. phenobarbital.

Available: in bottles of 100 tablets.

# IN THE ARTHRITIDES

For countless arthritics, regardless of the advancement of their affliction, treatment with massive dosage vitamin D has led to profound improvement, from dependable arrestment of the arthritic process to complete functional rehabilitation. Diactol is vitamin D<sub>2</sub> (calciferol), produced by selective irradiation of ergosterol, and is relatively free from intermediate irradiation products. In the recommended "individualized" dosage it is notably free from side actions. Administration over an adequate length of time, in a high percentage of cases, results in regression of periarticular soft tissue involvements, improves joint mobility, brings a new sense of well-being. The characteristic pain yields early, rendering the patient comfortable and more cooperative.

Physicians are invited to

## TRUSTWORTHY DISINFECTION of the SKIN

Iodine is a germicide upon which the surgeon can safely place his reliance. It is a valuable agent for pre-operative skin preparation, for it penetrates the epidermis and exerts a destructive action on the bacteria with which it comes in contact.

The method of skin disinfection with Iodine is both simple and rapid. More important . . . it also is trustworthy.

# WISH FULFILLMENT

**"If only there were a non-constipating  
alumina product . . ." *There is!***

'GELUSIL'\* Antacid Adsorbent is a wish fulfilled in peptic ulcer therapy. It contains an alumina gel which is non-reactive with gastric hydrochloric acid and does not break down, as do ordinary gels, into astringent, constipating aluminum chloride. 'GELUSIL' Antacid Adsorbent not only forms a colloidal shield protecting the inflamed peptic ulcer area, but effectively inactivates excess proteolytic pepsin. Through magnesium trisilicate, uniformly dispersed in its gel phase, 'GELUSIL' Antacid Adsorbent exerts a powerful and prolonged antacid-adsorbent antipeptic action.

Thus, within minutes, 'GELUSIL' Antacid Adsorbent provides relief which lasts for hours...Supplied in bottles of 6 and 12 fluidounces, and in boxes of 50 and 100 cellophane wrapped tablets. \*Trademark Reg. U. S. Pat. Off.

# BELBARB

AN

*Excellent*

SEDATIVE

*and*

HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, Belbarb *has always the same proportion of the alkaloids.*

**Indications:** Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

**Formula:** Each tablet contains  $\frac{1}{4}$  grain phenobarbital and the three chief alkaloids, equivalent approximately to 8 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but  $\frac{1}{2}$  grain phenobarbital per tablet.

# Seldom sick *but* never well

• Today, with our generously rationed American diet, there are few who develop frank vitamin deficiency syndromes.

But there is a great host of people who do not enjoy buoyant good health because they fail to obtain enough of these all-important accessory food substances.

*They are seldom sick but never well.*

For this great group, additional vitamins are necessary.

And what more convenient way is there to supply this need than to prescribe 'Avicap.'

One 'Avicap' a day supplies the minimum daily requirements of the six vitamins known to be essential in human nutrition.

'Avicap'—Registered Trademark

### Plain Talk, II

Many of us physicians are too preoccupied with the little trees of medicine to perceive the forest. We argue about details, procedure, and the like, endlessly, with each other. Thus we are prone to stress the differences of opinion which undoubtedly exist on many matters, while forgetting that we, the physicians, representing medicine, the public as the consumer, and government, the political agent of the people, are all in agreement as to the ultimate objective—better medical care for everybody. The people are interested in that.

We all want it. We all want it as soon as possible. The profession of medicine exists for no other reason than to provide it. The public rightly expects it from the medical profession—and gets it, by and large. Government can't do without it if it is to fulfill its constitutional pledge to promote the general welfare, of which the public health is a vital part.

The public knows something about insurance. It has bought billions of dollars worth of it, life, fire, accident, and the like, to its benefit.

Government knows about insurance, too. Because government is, after all, only the people when it does not forget and become biggity.

And the doctors, who are just people also, in spite of the language they use at times, are insurance-minded—couldn't carry on without it, in fact; life, fire, automobile, war-risk, accident, and all that.

So everybody is insurance-minded. And what is there to argue about? Spreading the cost? No; everybody agrees on that point. No argument. Ah! What are we proposing to insure against? The *costs of illness*. Sounds simple. Until you try it.

You can *assure* health only to a limited extent. That's preventive medicine and eugenics.

You can also *insure* against sickness. You can *insure* against the *costs* of being sick. If you know *how*, and *how much* the costs are and *how many* are going to be sick, and for *how long*. Plenty of room here for argument. Because you *have* to be right. You can't sell the insured people a gold brick. At least, not in this state. The law

says so. If you promise something to people for fulfillment in the future, and people pay you in advance for delivery, you have to deliver just what you promised them you would. And, furthermore, people must be satisfied with what they get as a result of that promise which you made to them and for the fulfillment of which *they paid in advance*, often far in advance.

Now, you can pay off your insurance obligation either in services or in money. Some think one way is better, some think the other preferable. But in any event, you propose to meet *costs* of illness, and most plain people think of meeting *costs* with *dollars*. They understand that. Years of experience with life and fire insurance have taught them. Thanks to the businessmen, who have made this plain, reasonably simple, and prompt.

And so medical care insurance to meet the *costs* of unexpected illness must be financially sound, must pay where needed with as little red tape as possible, and must satisfy a need of the consumer, at a *price* he can afford.

## Insure Your Self-Respect

We approach the time when, once every four years, the country works itself into a pre-election froth. Authentic polls of the voters tell us (up to the moment the ballots are counted) just what is going to happen. The simplest action of any public official is scrutinized for political significance. The newspapers and the radio become profound political oracles. And the elected representatives of the people mend fences furiously throughout the length and breadth of the land, so that no voter shall stray from the corral.

At such a time one is particularly impressed with the wisdom of medical leadership which, so far, has kept the profession free of political alliances or entanglements of any kind. Whatever party wins at the polls, whatever administration we may have to endure for another four years of broken promises, higher taxes, and gobbledygook, medicine at least can go about its business relatively unhampered by commitments to anybody but the sick. We say relatively because recently the fashion seems to be for

The medical profession thinks it has had sufficient experience with the plans which have been in experimental operation in this State for many years now, to be able to say that such voluntary insurance can be provided for the public.

Eventually, government will assist in the operation and furthering of such plans, in our opinion, rather than to operate its own scheme of compulsory "health" insurance disguised as social security or whatever seems at the moment to be politically expedient because, after all, government is only the people and the people get what they want in this country.

Eventually the people will want the kind of medical care insurance of which the doctors approve, if the doctors will advise the people about it, because the doctors have always dealt honestly with the people and the people respect that way of doing things. But the doctors will have to inform the people by every means at their disposal of the advantages of voluntary prepaid medical care.

political administrations to annoy the profession with proposals to come and play in the government backyard, and perhaps to dabble around a little with the boys at the public trough.

Fortunately, even though the public health is at a high level, there is still a great deal to do to improve it. This is our concern. It is a full-time job. And at the moment, election or no election, come hell or high water, an important part of that job is the promotion of voluntary medical expense indemnity insurance. It doesn't matter in the least what party wins the election. The country has magnificently survived and with patience endured all kinds—good, bad, or indifferent.

But unlike political administrations, medicine has to make good *all the time* or the people want to know "how come?" And the people will not take hokum for an answer.

The Medical Society of the State of New York is officially committed to the proposition of voluntary medical expense indemnity

insurance for the betterment of the individual and the collective health. It must make this system of self-respecting prepayment for medical care work with the help of the people themselves and free from political obscurantism. It will be quite a job, especially since we of medicine are short-handed; but no matter, we can do it and call it by its right name into the bargain.

Medicine is not hampered by the necessity for fence-mending, elections, or any commitment to compel anybody to do anything about medical indemnity insurance, or the "political angles" inherent in any government-controlled project.

When medicine deals directly with the people themselves on a voluntary basis there is safety and security for both.

## Diphtheria

During the last twenty years we have seen a marked decrease in the incidence of diphtheria concomitant with and undoubtedly conditioned by the increasing use of various artificial immunizing agents. But the protection level against diphtheria for any community may be taken as the summation of its natural and its artificial immunization levels, modified by the prevailing contact rate, population flux, crowding, and social interchange, as well as the virulence of the organism. As community experience with the disease decreases, it would seem that administration of diphtheria toxoid must increase to compensate for it.

In a special article in this issue, page 2138, Dr. Berwyn F. Mattison, M.P.H., discusses a recent small outbreak of diphtheria in a New York State community, with suggested

steps to maintain the necessary level of community protection. These include higher preschool protection rate, reimmunization of all children on entrance to school, administration of complete courses in every individual immunized.

Of special interest to school physicians, we recommend a thoughtful reading of this study by general practitioners in particular. If this situation is found with respect to diphtheria, what of the other communicable diseases?

More and more attention must be paid, apparently, to the mechanisms for specific prevention and the maintenance of a high level of immunity by artificial means if we are to avoid living under a sense of false security. More studies of this nature should be encouraged.

## Universal Military Training

It is with the utmost satisfaction that we note General George Marshall's directive to those planning America's postwar military policy. His advocacy of the fundamental principle of a citizens' army, based on universal service, will be supported, we feel, by all physicians, as the only democratic approach to the problem. The need for armed force adequate to keep the peace, or to meet war, should it come, will be obvious, we hope, to all, and particularly to the medical profession.

The physicians of the country have been especially privileged in being able to observe at first hand through their services to the draft boards and the examining teams at the induction centers, and their honorable service with troops in the field, the tragic results of unpreparedness and the necessity for

a continuing policy of universal military training.

The physicians will agree with Maj. Gen. Paul R. Hawley in his recent speech at the Cincinnati College of Medicine,<sup>1</sup> that the restoration to health in this war of about 97 per cent of our wounded is commendable. They have only done the job that was expected of them with the aid of the latest findings of medicine and all the resources of modern surgery. But this applies only to the wounded. Even modern medicine can do nothing for the dead, and relatively little for the broken in spirit who, though healed of their wounds, will remain for more years than we like to contemplate a living reproach to our recent national policy of unpreparedness, fatuous stupidity, and criminal neglect.

The blame for this lies squarely at the door of every citizen in the nation. Theirs the indifference, theirs the blame, theirs the "it can't happen here" attitude that put the myriad white crosses in U.S. military cemeteries twice in a quarter century. Theirs the pinch-penny squealing that has influenced their elected political representatives to deny necessary appropriations to the military and naval establishments. "As late as March of 1940," says Walter Lippmann,<sup>2</sup> "War Department estimates for a small number of replacement airplanes were cut by the House of Representatives to 57 planes." Theirs the blind stupidity that must never occur again. And yet it is to be expected that the corrosion of enemy propaganda will shortly begin to seep through its usual channels to undermine again and to destroy our resolution never again to be caught unaware and unprepared. This propaganda must be combated.

Physicians will be advised that a Citizens' Committee for Universal Military Training of young men has been in process of organization for some time. The Committee within the Second Service Command has already been organized to inform the public and to secure nation-wide support in favor of the promotion of useful citizenship and the unity and security of the United States.<sup>3</sup>

This will be good news to those medical men in the armed forces abroad and at home who are in a position to see for themselves the folly of neglect of universal military training. It is sincerely to be hoped that every medical man in the nation will uphold General Marshall's hands and do his or her part in every way, starting *right now*, to assist in supporting this program of training.

## Make it Brief

As time wears on the help and energy which would have accrued to the several medical societies, county and state, becomes more conspicuous by its absence. The older men who are carrying on to the limit of their ability are finding their reservoir of force and available time depleted by the demands of their private practices and the increasing burden of their hospital and clinic work. Many have had no vacations; some but a few days. Responsibilities have multiplied.

Can something be done further to ease the accumulating burden on those physicians who serve the people and the medical societies gratuitously on the numerous committees of organized medicine? We think it can. Many of the meetings are too long-drawn-out.

True, something has been done to cut

the number of meetings to a minimum, but we contend that in many instances they are still too long-drawn-out. Freedom of speech can be lost through abuse of the right as well as in other ways possibly less painful.

Agenda of meetings might frequently be cut with much benefit in conservation of busy physicians' time. Discussions might often be briefer with no loss to the subject under consideration. Presiding officers, by holding speakers and discussants strictly to the point, could be a great help.

Many of our meeting habits have been acquired in former times when leisure was more than a word in the dictionary. Those times will doubtless return one day. But, in the meantime, make it brief.

The less you say today, the less you may have to take back tomorrow.

## Erratum

The editorial entitled "Poliomyelitis" appearing on pages 1760 and 1761 of the August 15 issue of the *JOURNAL*, in the letter of Dr. James E. Perkins, on page 1761, column two, line eighteen read "possible" for "impossible." It is regrettable that this error has changed the meaning and we reproduce the entire sentence in its proper sense herewith:

"I think it is important, therefore, to have the physicians throughout the State aware of these

changes, and that the reason for the changes is that it has become increasingly clear that in view of the large number of nonparalytic cases of the disease, which will never be recognized as cases of poliomyelitis infection, and thus can never come under governmental restriction although perfectly capable of spreading the infection, it is impossible to control the spread of the infection through government regulation."

# PROBLEMS OF TREATMENT OF TROPICAL DISEASES IN RETURNING MILITARY PERSONNEL

HENRY E. MELENBY, M D, New York City

THE most important problems in the treatment of tropical diseases in returning military personnel, as seen at the present time, are malaria and filariasis. Other common diseases which may be encountered with varying frequency are amebiasis, bacillary dysentery, hookworm, and other intestinal worms and protozoa. Isolated cases of visceral or cutaneous leishmaniasis, African trypanosomiasis, schistosomiasis, and leprosy may appear. It is not likely that cases of cholera, plague, yaws, relapsing fever, louse-borne typhus, mite-borne typhus, or yellow fever will be brought into the country.

## Malaria

The treatment of malaria in returned military personnel has two principal aspects, first, the treatment of relapses of vivax (tertian) malaria, and, second, the recognition and treatment of early cases of falciparum (estivoautumnal) malaria.

The relapses of vivax malaria occur mainly in troops who have taken quinacrine (atabrine) as a suppressive measure in forward combat zones where malaria is hyperendemic, and where other malaria control measures have been impossible. Neither quinacrine nor quinine is a true prophylactic against malaria. They have no up parent action against the sporozoite introduced by the mosquito, but merely suppress the infection after the parasites have entered the red blood cells. It seems probable that many falciparum infections are entirely eliminated by suppressive treatment with quinacrine, but most, if not all, of the persons infected with vivax develop clinical malaria within a few weeks after suppressive treatment is discontinued. This seems to be a reasonable explanation of the fact that, although falciparum infection is much commoner than vivax in most parts of the tropics, most of the clinical cases of malaria in our troops who have taken suppressive treatment in those areas are caused by vivax. It is well known that vivax infections relapse much more commonly and repeatedly than falciparum infections. Some of our returned troops have had ten or more relapses, and some of them will undoubtedly be discharged to civilian life and have later relapses.

The reason why vivax infections are so often

not eliminated by the usual course of therapeutic treatment is not yet known. Either the asexual cycle continues in tissues such as the spleen pulp where drugs cannot reach the parasites in sufficient concentration, or there is an exocytrocytic cycle in the reticuloendothelial cells, such as has been described in certain species of bird malaria, and which is resistant to our present antimalaria drugs. It is also possible that when cases are treated as soon as symptoms occur specific antibodies do not have time to develop and assist in eradicating the infection.

Despite the recently announced synthesis of quinine, this drug is not likely to be available for several years for the treatment of malaria by mouth, and quinacrine must be depended upon chiefly. Quinacrine, like quinine, affects mainly the asexual parasites which cause the symptoms of the disease. The course of treatment which was originally advocated was 0.1 Gm. three times a day for five to seven days. Recent studies have shown, however, that although quinacrine is quickly absorbed from the intestine it is rapidly taken up by the fixed tissues, and does not reach an effective concentration in the blood plasma and red cells until the tissues are fairly well saturated. For this reason it is now advocated that quinacrine be given initially in doses of 0.2 Gm. every six hours for five doses in order to raise the blood concentration to an effective level, and that this be followed by 0.1 Gm. three times a day for the succeeding six days. Since quinacrine is eliminated from the body very slowly, it is effective for several days after treatment is discontinued. If patients relapse after such a course of treatment it may be advisable in a subsequent relapse to continue the 0.2 Gm. dosage every six hours for six to eight doses or to continue the 0.1 Gm. dosage three times a day for two to three weeks.

Toxic symptoms from quinacrine have been observed, strange to say, mainly when it is administered in small doses for suppressive treatment rather than in full therapeutic doses. These symptoms consist of nausea, vomiting, and diarrhea when troops are on active duty. The yellow discoloration of the skin from therapeutic doses is not jaundice, but is due to the deposition of the acridine dye, and can be ignored. The only other toxic symptoms are very rare mental disturbances. If these occur, quinine should be substituted in treatment.

The use of plasmochin to supplement quin-

From the Department of Preventive Medicine, College of Medicine, New York University.

acrine or quinine has not proved to be of significant value in our armed forces, and since it is dangerously toxic its use is to be discouraged.

Totaquine, which contains a small percentage of quinine supplemented by the other three alkaloids of cinchona—namely, quinidine, cinchonine, and cinchonidine—is practically as effective as quinine for oral medication. It has been adopted by the *United States Pharmacopoeia*, but is not yet generally available. If it does become available it can be used effectively in doses of 0.6 Gm. three times a day for seven days. Some relapse cases may require the continuation of treatment at one half of this dosage for two to three weeks.

Practically the only indication for parenteral therapy in malaria is acute falciparum infection.<sup>1</sup> If the parasite count is above 50,000 per cubic millimeter of blood, or if the clinical symptoms are severe in the presence of a lower parasite count, immediate parenteral treatment should be instituted. Such cases are not likely to be seen in troops discharged to civilian life, but they have been seen in individuals returning from overseas by air, who have become infected just before leaving the tropics and have developed their first symptoms after arrival in this country. The onset of these cases is often insidious, with coryza, mild malaise, or diarrhea, and they have sometimes progressed rapidly into coma before being recognized. Physicians must be on the alert to suspect such cases and to make repeated blood examinations at frequent intervals. In such cases quinacrine dihydrochloride in solution may be administered intramuscularly in simultaneous doses of 0.2 Gm. in each buttock, and the dose may be repeated at intervals of eight to twelve hours if the condition remains serious. Treatment by mouth should be started as soon as possible according to the schedule outlined above in order to maintain a high blood level. Quinine dihydrochloride in solution is still available, and may be preferred. It is probably best to administer it intravenously in doses of 0.5 Gm. diluted with 200 cc. of normal saline solution, glucose, or plasma. The infusion must be given slowly and the blood pressure must be watched carefully, since quinine may cause it to fall. If the systolic pressure is below 100 it may be advisable to administer epinephrine before giving quinine intravenously, or the epinephrine may be given in the infusion with the drug. A concise discussion of the treatment of malaria is presented in Circular Letter 153, issued by the Surgeon General of the Army and published in the *Journal of the American Medical Association* for September 25, 1943.<sup>2</sup>

In order to obtain accurate diagnosis of the species of malaria parasite involved and an

estimate of the intensity of the infection, physicians should have access to a laboratory in which the technicians are well trained in both thin-smear and thick-drop blood examinations. Both a thin-smear and a thick-drop preparation should be made in every case, either on the same slide or on separate slides, and the physician should be sure that these are made in the most approved manner so that examination will be reliable. The thick-drop preparation is particularly valuable in relapses or patients with mild symptoms in whom the parasites may be few, and also in acute falciparum infections where most of the parasites may be stuck to the walls of capillaries. Technicians should receive special training in the best staining methods and in the identification of parasites in thick-drop preparations, in which the blood has been hemolyzed and the parasites are more difficult to identify. Every laboratory should possess Bulletin No. 180 of the National Institute of Health, entitled "Manual for the Microscopical Diagnosis of Malaria in Man." This can be obtained from the Superintendent of Documents in Washington, D.C., at a cost of 30 cents.

### Filariasis

The problem in the treatment of filariasis caused by *Wuchereria bancrofti* is primarily the lack of a drug which is effective against this worm. The adult worm inhabits the lymph vessels and lymph nodes and causes attacks of acute lymphangitis which may ultimately lead to lymphatic obstruction and elephantiasis. Several hundred of our troops have become infected, particularly in certain islands of the South Pacific, and have been invalided home because of acute lymphangitis or lymphadenitis or involvement of the lymph vessels of the scrotum. These symptoms often appear as early as three months after infection, when the adult worms are still immature. The attacks are accompanied by fever and redness, swelling, and pain of the part involved. They last for a few days and usually recur at intervals of a few weeks. They appear to be an allergic phenomenon due to the presence of the worm. In native patients with local abrasions of the skin hemolytic streptococci have been suspected of contributing to the acute manifestations.

Most patients who are removed from the endemic areas in order to avoid repeated infection never develop elephantiasis, and it is hoped that this will be the case in our troops. There is a strong psychologic factor involved, in that infected patients have seen elephantiasis of the scrotum and legs in natives of the endemic areas, and fear impotence and deformity in their own cases. They may be assured that impotence

will not occur, and that deformity is very unlikely to develop.

Diagnosis in early cases is mainly based upon symptoms, since the worms are immature and no microfilariae are found in the blood. A few cases have been confirmed by finding young worms in lymph nodes removed at biopsy. Some patients will probably have recurrences of the acute manifestations after discharge from military service, and will come under the care of civilian physicians. In a few individuals microfilariae may later be found in the blood without any previous history of lymphangitis. Some such cases have been discovered in Puerto Ricans examined for admission into the armed forces. In some parts of the world the microfilariae have a definite nocturnal periodicity in their appearance in the blood stream, while in other areas there is a diurnal periodicity or larvae may be found at any time of the day or night.

Search is now being made for a drug to cure this infection. Preliminary observations with an organic antimony preparation are encouraging, and other preparations are being explored. Even if no effective chemotherapy is discovered, it is very unlikely that new endemic foci of filariasis will be established in this country. The only one which has ever existed was in and about Charleston, South Carolina, and this has apparently died out within recent years because of mosquito control. Although the worm can be transmitted by several genera of mosquito, a large human reservoir and an abundance of mosquito vectors are necessary to maintain transmission.

### Other Common Tropical Diseases

Amebiasis or infection with *Endamoeba histolytica* is present throughout almost the entire world. The chief danger in connection with our armed forces is that certain strains of the ameba acquired in the tropics may have a higher degree of pathogenicity than most of the strains present in this country, and that infected troops may develop acute amebic dysentery or liver abscess after they are discharged from military service, or that they may transmit the infection to other members of their families or, through polluted water, to larger groups of people. The tendency of amebiasis to become chronic and resistant to chemotherapy and the functional disturbance which may follow scarring of the intestine may present problems to civilian physicians. Liver abscess may occur months or years after the infection is acquired without any previous history of clinical dysentery. In the treatment of amebiasis emetine hydrochloride has been depended upon too greatly in the past. Although very effective in overcoming acute symptoms, it acts

only on tissues which are furnished with a good blood supply, and probably has little effect on amebae in the lumen of the intestine. It is also toxic to the heart muscle, and many persons have suffered permanent damage to the heart from excessive use of this drug. It should be administered intramuscularly, never in doses exceeding 60 mg per day, and rarely, if ever, longer than six days at a time. It is wise to follow the patient with the electrocardiogram before and at intervals during treatment and to stop treatment if any changes occur. Emetine is necessary in amebic hepatitis and liver abscess, and should be started as soon as a diagnosis is made. Sometimes its early use makes surgical intervention unnecessary. In any case, it is advisable to administer emetine, if possible, for three or four days before drainage is instituted, in order to stop the progress of the infection. Drainage of a liver abscess by cannula is much to be preferred to an open operation. In acute amebic dysentery it is usually necessary to administer emetine only for the first three or four days, and treatment by mouth should be started at the same time, using one of the iodine preparations, namely, chiofon, vioform, or diodoquin, or the arsenic preparation, carbarsone, in order to eliminate the intestinal infection. These preparations can be administered for ten days at a time, and it is wise to alternate them for two or three consecutive courses in order to avoid relapses.

The diagnosis of amebiasis is often a difficult technical procedure. Laboratory technicians must be well trained in the differentiation of *Endamoeba histolytica* from the nonpathogenic amebae and from body cells. Specimens should be examined as soon as they are passed and concentration methods for cysts should be employed both in original diagnosis and in follow up. It is wise for the physician to assure himself of a correct diagnosis before instituting treatment, as other serious diseases are often mistaken for amebiasis.

Bacillary dysentery is one of the commonest diseases of the armed forces in camps in this country and in the tropics. Fortunately, most of the cases have been relatively mild, and the severe Shiga strain has rarely been encountered thus far. With the advance of our troops into other occupied areas under combat conditions this strain may be encountered more frequently. Fortunately also, the sulfonamide drugs have proved to be very effective against bacillary dysentery, so that chronic cases are much less likely to develop with the use of these drugs. Symptomless carriers occur in considerable numbers in the presence of an epidemic, and a few of these carriers may harbor the infection after return to civilian life, and give rise to sec-

acrine or quinine has not proved to be of significant value in our armed forces, and since it is dangerously toxic its use is to be discouraged.

Totaquine, which contains a small percentage of quinine supplemented by the other three alkaloids of cinchona—namely, quinidine, cinchonine, and cinchonidine—is practically as effective as quinine for oral medication. It has been adopted by the *United States Pharmacopoeia*, but is not yet generally available. If it does become available it can be used effectively in doses of 0.6 Gm. three times a day for seven days. Some relapse cases may require the continuation of treatment at one half of this dosage for two to three weeks.

Practically the only indication for parenteral therapy in malaria is acute falciparum infection.<sup>1</sup> If the parasite count is above 50,000 per cubic millimeter of blood, or if the clinical symptoms are severe in the presence of a lower parasite count, immediate parenteral treatment should be instituted. Such cases are not likely to be seen in troops discharged to civilian life, but they have been seen in individuals returning from overseas by air, who have become infected just before leaving the tropics and have developed their first symptoms after arrival in this country. If the systolic pressure is below 100 it may be advisable to administer epinephrine before giving quinine intravenously, or the epinephrine may be given in the infusion with the drug. A concise discussion of the treatment of malaria is presented in Circular Letter 153, issued by the Surgeon General of the Army and published in the *Journal of the American Medical Association* for September 25, 1943.<sup>2</sup>

In order to obtain accurate diagnosis of the species of malaria parasite involved and an

estimate of the intensity of the infection, physicians should have access to a laboratory in which the technicians are well trained in both thin-smear and thick-drop blood examinations. Both a thin-smear and a thick-drop preparation should be made in every case, either on the same slide or on separate slides, and the physician should be sure that these are made in the most approved manner so that examination will be reliable. The thick-drop preparation is particularly valuable in relapses or patients with mild symptoms in whom the parasites may be few, and also in acute falciparum infections where most of the parasites may be stuck to the walls of capillaries. Technicians should receive special training in the best staining methods and in the identification of parasites in thick-drop preparations, in which the blood has been hemolyzed and the parasites are more difficult to identify. Every laboratory should possess Bulletin No. 180 of the National Institute of Health, entitled "Manual for the Microscopical Diagnosis of Malaria in Man." This can be obtained from the Superintendent of Documents in Washington, D.C., at a cost of 30 cents.

### Filariasis

The problem in the treatment of filariasis caused by *Wuchereria bancrofti* is primarily the lack of a drug which is effective against this worm. The adult worm inhabits the lymph vessels and lymph nodes and causes attacks of acute lymphangitis which may ultimately lead to lymphatic obstruction and elephantiasis. Several hundred of our troops have become infected, particularly in certain islands of the South Pacific, and have been invalided home because of acute lymphangitis or lymphadenitis or involvement of the lymph vessels of the scrotum. These symptoms often appear as early as three months after infection, when the adult worms are still immature. The attacks are accompanied by fever and redness, swelling, and pain of the part involved. They last for a few days and usually recur at intervals of a few weeks. They appear to be an allergic phenomenon due to the presence of the worm. In native patients with local abrasions of the skin hemolytic streptococci have been suspected of contributing to the acute manifestations.

Most patients who are removed from the endemic areas in order to avoid repeated infection never develop elephantiasis, and it is hoped that this will be the case in our troops. There is a strong psychologic factor involved, in that infected patients have seen elephantiasis of the scrotum and legs in natives of the endemic areas, and fear impotence and deformity in their own cases. They may be assured that impotence

# PERIARTHRITIS OF THE SHOULDER JOINT

## Classification, Pathology, and Treatment

JAMES M. TARSY, M.D., Brooklyn, New York

**PERIARTHRITIS** of the shoulder, or its more descriptive synonym, "frozen shoulder," may be induced by a wide variety of surgical and medical conditions. Our interest in this paper, however, lies mainly in the medical phases of periartthritis as well as in those surgical entities which enter into the picture and which are ultimately capable of leading to this disability.

In the past, periartthritis of the shoulder has been dealt with chiefly as an orthopedic entity. That it is of equal interest to the medical man, however, is attested to by the similarity of the so called primary form of periartthritis to the rheumatic syndrome. The frequency with which patients suffering from painful shoulders present themselves in various arthritis clinics throughout the country, the number of dissimilar, if not bizarre, diagnoses made, and the interest that these cases present from a medical standpoint, make it incumbent upon the medical man to have a workable understanding of this condition.

Of the entities which involve the shoulder joint, periartthritis, perhaps, has the distinction of being the most confusing. This confusion is reflected in its many phases: arthritis, rheipathic monarticular arthritis,<sup>1</sup> neuritis, bursitis, subdeltoid bursitis,<sup>2</sup> subacromial bursitis,<sup>3</sup> adherent subacromial bursitis,<sup>4</sup> "frozen shoulder,"<sup>5</sup> periarticular fibrositis, tendinitis of the short rotators,<sup>6</sup> primary tendinitis,<sup>7</sup> obliterative subacromial bursitis,<sup>8</sup> peritendinitis calcarea,<sup>9</sup> and Duplay's disease.<sup>10</sup>

Both Codman's and Wilson's approach<sup>9</sup> to this entity reflect the uncertainty surrounding its cause and its pathology. Codman in "Tendinitis of the Short Rotators," prefaces his chapter as follows: "This is a class of cases which I find difficult to define, difficult to treat and difficult to explain from the point of view of pathology." In the same vein Wilson<sup>9</sup> prefaces his paper with a similar statement: "It is with trepidation that the last entity is introduced. It is the so called 'periartthritis' or 'tendinitis' or 'frozen shoulder'." My own particular reaction in speaking of this condition is very much akin to that of Codman and Wilson.

## Classification of Periartthritis

As already mentioned, the term periartthritis is very loosely applied and is representative of any

number of shoulder conditions accompanied by pain and functional limitation. The result is almost Babylonian confusion. It is believed, however, that we are here dealing with a definite clinical entity and that the term "periartthritis" should be applied only on the basis of certain clinical and pathologic criteria, and not solely on pain and limited mobility.

As a case in point, the picture described by Dickson and Crosby<sup>10</sup>—pain and loss of function accompanied by limitation of motion—does not necessarily indicate periartthritis. An immediate injury to the shoulder is often followed by partial loss of function and limited mobility. This may be merely the result of pain and spasm, no fibrosis, tendinitis, or other organic pathology exists. By the same token, calcification, partial rupture of the supraspinatus tendon, and bursitis may each precede and ultimately lead to periartthritis, but they are not periartthritis. It is important, therefore, that in referring to any given shoulder condition we all speak the same language. This common language, as in all human intercourse, is the primary basis of understanding.

Study of this condition, as well as the literature thereon, points to two separate forms or groups of periartthritis (Groups I and II), each having certain distinct causative and pathologic characteristics.

Since the causative factors in one group (Group I) are still in doubt, a more concise terminology is suggested: primary periartthritis (periartthritis of uncertain origin). Conversely, since cases falling in the second group (Group II) follow a more or less definite causative sequence, the term "secondary periartthritis" (periartthritis of known origin) is proposed.

It is believed that the confusion existing in this symptom complex is partially the result of failure to differentiate between these two forms of the disease. That this differentiation is not merely of academic importance is substantiated by clinical, causative, and therapeutic differences. Militating against this distinction are those cases in which no causative or pathologic differences can be made out.

As a variant, a corresponding terminology of metabolic periartthritis and traumatic or mechanical periartthritis, respectively, might be substituted for these two forms of the disease.

The term "metabolic," however, is too circumscribed for a condition the exact cause of which is as yet in doubt. This term would likewise ex-

Chief Arthritis Clinic, New York Post-Graduate Medical School.

clude infectious or toxic causes. The same criticism may be applied to the term "traumatic" or "mechanical," since not all cases of periarthritis falling in Group II are the result of trauma or mechanical irritation of the subacromial bursa by a ruptured calcium deposit in the supraspinatus tendon.

All in all, the terminology described above, though having certain inherent faults, might aid in clarifying a common and involved clinical situation.

### **Primary Periarthritis {Periarthritis of Uncertain Cause}**

1. Onset related to no immediately demonstrable cause.
2. Supraspinatus tendon and subacromial bursa not primarily involved.
3. Supraspinatus calcium deposit usually absent.
4. Trauma, whenever present, relatively insignificant.
5. Systemic predisposing factors present and predominant.
6. Initial pathology mostly confined to periarticular tendons (spasm and fibrosis).
7. Terminal pathology (extensive periarticular fibrositis) involving tendons, muscles, capsule, and other structures.

### **Secondary Periarthritis {Periarthritis of Known Cause}**

1. Onset frequently related to trauma.
2. Initial pathology usually in supraspinatus tendon and subacromial bursa (calcification, inflammation, and formation of adhesions).
3. Presence of preceding degenerative changes in supraspinatus usually noted.
4. Systemic factors not present nor predominant.
5. Pathology involving one, several, or all of following structures present: supraspinatus, subacromial bursa, capsule, periarticular tendons.

Codman, in his book, *The Shoulder*,<sup>1</sup> devotes one whole chapter to periarthritis, "Tendinitis of the Short Rotators," and part of another, "Arthritis, Periarthritis, and Bursitis of the Shoulder Joint." In the former he refers to what I have here called primary periarthritis as essentially a tendinitis, with only secondary involvement of the bursa. He also refers to it as adherent subacromial bursitis or "frozen shoulder." In the latter chapter he speaks of it as a periarthritis. Whereas Codman separates this entity into two apparently distinct groups, this distinction is somewhat hazy, at times difficult

to follow, and the nomenclature somewhat confusing.

P. D. Wilson's exposition of this subject<sup>5</sup> comes closest to my interpretation of the clinical and pathologic picture that we are called to deal with. Wilson recognizes a distinct symptomatology for primary periarthritis in what he describes under the simple title of "Periarticular Adhesions (Tendinitis)" and feels that "there can be no doubt that we are here dealing with a separate disease entity." Under "treatment" he refers to it as a primary tendinitis. The gap between primary tendinitis and primary periarthritis is a small one.

### **Primary Periarthritis**

Little is known of the exact cause or nature of the pathologic changes in this condition. The clinical picture and what is known of its cause and its pathology, however, point to a separate and distinct disease entity.<sup>5</sup> X-ray is usually negative, though in certain instances several flecks of calcium deposit in the supraspinatus tendon have been found.<sup>5</sup> Operation fails to reveal any calcification of the supraspinatus tendon, adhesions around the subacromial bursa, or partial rupture of the collagenous fibers of the supraspinatus.<sup>1,5</sup> A history of trauma is absent, vague, or not clearly associated with the onset of symptoms. Physical examination fails to reveal any swelling or focal point of tenderness, though there may be generalized sensitiveness about the shoulder. Active and passive extension, abduction, and rotation are markedly restricted. Attempt to elevate or abduct the arm by sheer force results in considerable pain. Scapulohumeral motion is frequently absent. Manipulation under anesthesia results in audible sounds of snapping adhesions followed by complete freeing of shoulder movements.<sup>5</sup>

Onset is usually gradual and preceded by a history of a painful catch in the region of the greater tuberosity. In time the patient becomes aware of a sense of stiffness in the shoulder, accompanied by restricted motion.<sup>5</sup> In certain instances pain is completely lacking, the patient becoming aware of his condition by an increasing sense of disability. Some patients have little restriction and much pain; others have stiff, painless joints with varying degrees of pain and disability ranging in between.<sup>1</sup> Pain is often increased at night and is aggravated by pressure caused by lying on the affected shoulder. This night pain is often compared to that of a dull toothache. Ofttimes the patient consults a physician not because of the pain, which may be bearable, but because of inability to elevate the arm. In several of my cases extension was limited to the point of making it impossible to board a bus or trolley.

### Cause of Primary Periarthritis

That an important systemic common denominator prevails in this form of periarthritis is suggested by its relation to sex, age, occupation, and menopause.

It is significant that it is more common in women of the so-called leisure class, whereas secondary periarthritis is more commonly seen in laborers.<sup>1</sup> According to Codman's studies 58 per cent occurred in women, the average age in 100 patients treated being 53 years. It is also significant that it is rarely encountered in young persons under 25. This is suggestive of physiologic or metabolic imbalance as a causative factor.<sup>10, 11</sup> An equally important factor, as in so-called osteoarthritis of the menopause, is that of estrogen deficiency.<sup>12</sup> The importance of hypothyroidism is also worthy of note and may have similar implications here. This relation of hypothyroidism to the rheumatic syndrome has been stressed by Dunn.<sup>13</sup> Toxemia of bacterial or nonbacterial origin has also been implicated in both forms of periarthritis.

A parallel to contraction of the short rotator group and other muscles in this condition is commonly seen in rheumatoid arthritis. In the latter, disability of the shoulder, ulnar deviation, contraction of the hamstrings with flexion deformity in the knee are perhaps all suggestive of the effect of a systemic irritant which causes the muscles and tendons to contract. Contracture also insures a position of ease for the joint, this, in time, may be followed by actual shortening.

Further evidence in favor of a systemic cause is the average of spontaneous improvement within two years,<sup>1</sup> the value of bed rest alone as a therapeutic aid, absence of a distinct traumatic history, occasional bilateral involvement, probable higher incidence in the left shoulder,<sup>5</sup> and the consecutive involvement of both shoulders.

As to pathogenesis, a conditioning of the periarthritic structures might be assumed, as a result of which nature, in an effort to ward off pain and injury, insures a position of ease by limiting mobility. This is the anatomic position in which the arm hangs naturally down on the side of the body and in which the joint is really in a state of flexion. Thus "tendinitis" or contraction of the periarthritic ligaments and finally fibrosis, occurs. It is a protective mechanism frequently seen in proliferative arthritis as well, in such joints as the shoulder, elbow, wrist, knee, and sometimes those of the foot, one which in time assumes a parapsysiologic or purposeless role.

In my observation of a substantial number of acute cases of painful and disabled shoulders, I have been amazed at the rapidity of the involvement of the muscles surrounding the shoulder.

Within a relatively short period of the date of onset the degenerative-inflammatory-fibrotic process had involved the tendinous insertions. Codman,<sup>1</sup> Dick, Hunt, and Ferry<sup>14</sup> noticed atrophy of the spinatus muscles if the symptoms lasted more than a few weeks.

### Pathology of Primary Periarthritis

It has been pretty well proved pathologically that we are not dealing here with an arthritis. Outright exclusion of this type of periarthritis from the group of rheumatic entities is not possible at this time, however.

Codman<sup>1</sup> refers to this group as a tendinitis of the short rotators. However, evidence points to the fact that other tendons are involved, as well as the capsule, ligaments,<sup>9</sup> and perhaps even the muscles. The pathology, in advanced cases, therefore, is undoubtedly extensive, involving all or most of the structures forming the shoulder girdle. Analysis of the reports of Codman,<sup>1</sup> Brickner, Carnett, and Harbin<sup>15</sup> shows that even in secondary periarthritis, with excision of the bursa or removal of the calcified deposit, adhesions, when present, must be broken by manipulation before the arm can be brought into abduction and external rotation.<sup>4</sup> The exact location of these adhesions, however, has, according to Wilson,<sup>5</sup> never been definitely ascertained.

Wilson,<sup>5</sup> with his finger in the bursa, manipulated three of these shoulders and felt the snapping of adhesions in the capsular structure beneath his finger and anteriorly in the region of the subscapularis tendon. He is of the opinion that the adhesions lie in the substance of the tendinocapsular structure, whence they may extend to involve either underlying or overlying tissues. Like Codman, he is of the opinion that the process probably starts as a tendinitis which on subsiding leaves a thickened, inelastic capsule adherent, beneath, to the edges of the articular cartilage and above, to the adjacent soft tissues.

Wilson is not sure whether this tendinitis is a true inflammatory process due to low grade infection or, as he expresses it, "still another manifestation of the attritional and degenerative changes to which this structure (the supraspinatus tendon) is particularly liable."

Codman's designation of this condition as adherent subacromial bursitis would lead us to believe that the bursa is either primarily involved or, at least, involved most of the time. This has not been substantiated either by Codman himself or by other students of this condition.<sup>5, 9</sup> Wilson<sup>5</sup> explored the subacromial bursa with disappointing findings. In only one case was the bursa obliterated by adhesions. In two cases the appearance of the bursa was fairly normal, although it seemed small. In one other case the

bursa appeared normal, but the tendinocapsular cuff lying beneath it was of a uniform red color, indicating extensive hyperemia. He was, therefore, led to believe that this was an early case with the inflammatory process still present and active.

Kendrick<sup>3</sup> mentions the pathologic changes observed by Duplay on necroscopy in a 53-year-old man who died of pneumonia and whose shoulder had been manipulated two months before his death. On the affected side the deltoid was paler than normal; the subdeltoid tissue was fibrous, exhibiting dense bands running to the upper end of the humerus. The subacromial bursa was obliterated. The tendons of the supraspinatus and infraspinatus had lost their polish, as had also the inferior surface of the acromion. It was inferred that the chief lesion was in the subacromial bursa, with extension to neighboring structures. Under the inferior surface of the deltoid could be seen ruptured adhesions. The articular capsule was somewhat thickened but the articular surfaces were normal.

According to Kendrick<sup>3</sup> the major adhesions seem to be over the inferior and anterolateral aspects of the joint. Some of these adhesions are broken as the arm is abducted and externally rotated; others, as the arm is internally rotated.

In seven patients operated upon by Bosworth<sup>6</sup> massive, obliterating adhesions requiring sharp dissection were found. These adhesions were unusually dense about the subscapularis tendon.

It is my belief, from a study of these cases, that the tendinous or the musculotendinous structures are first involved. Degeneration, inflammation, and disuse result in a fibrotic process which subsequently extends to the capsule, the ligaments, and even the muscles. In short, we are here really dealing with a periarticular fibrositis. This fibrotic process is probably on a rheumatic or toxic basis and may be abetted by a number of coexisting factors both systemic and local, viz., metabolic imbalance, glandular dyscrasia, focal infection, toxemia, repeated subminimal trauma, disturbed circulation,<sup>10</sup> one or all of which may be present.

This tallies with Dickson and Crosby's concept of "a common underlying alteration in the physical state"<sup>10</sup> and Codman's evolutionary theory of mechanical disadvantage.<sup>1\*</sup> Therefore, because of its peculiar anatomy,<sup>†</sup> during fibrosis

this joint tends to become fixed in a position of ease. There are many such parallels in the human body in which fibrosis is localized in certain areas or groups of muscles.<sup>16</sup> The shoulder, because it is naturally in a state of flexion, tends to become immobilized in this position. It may very well be that an ordinarily intangible rheumatic process commonly known to the rheumatologist may be the common denominator in many such apparently unrelated processes.

Of the muscles and tendons taking part in this clinical syndrome I have been able to find little mention in the literature. Codman<sup>1</sup> fleetingly refers to an inner and outer group of muscles but does not stress their pathology. The inner group, most commonly involved, according to this investigator, comprises the short rotators; the outer group, only occasionally involved, the deltoid, the pectorals, and the teres major. Pinner and Staderman<sup>7</sup> also allude to an inner and outer group as controlling motion of the shoulder, but fail to mention their role in this condition.

Study of the "frozen shoulder," the anatomy of the muscles, and their relation to the bony parts to which they are attached, leads me to concur in the belief that, specifically, two groups of muscles and their tendons are involved: an inner group comprising the supraspinatus, infraspinatus, teres minor, and subscapularis; an outer, comprising the deltoid, pectoralis major, latissimus dorsi, and long head of the triceps. These structures, however, may not all be involved at the same time.

The inner group of muscles, arising from the scapula and their fasciae, stretch laterally to the humerus to be inserted into the greater or lesser tuberosity.<sup>17</sup> These short rotator tendons are, likewise, all attached to the capsule of the shoulder joint.<sup>1,5,9,17</sup> Contraction or fibrosis of these structures would, as is demonstrable by a study of the figures here presented, tend to bind or immobilize the humerus against the glenoid and inhibit scapulohumeral motion. The teres major, similar in its origin and mechanics to this inner group, also appears to play a related role in pathology.<sup>1</sup> Of the outer group, the pectoralis major, the latissimus dorsi, and the long head of the triceps are most frequently involved. The deltoid, though commonly atrophied, in my opinion, rarely inhibits mobility. The remaining muscles of this group arise mainly from the trunk (latissimus dorsi), the thorax and clavicle (pectoralis major), and the infraglenoid tuberosity (long head of the triceps), and stretching laterally, are inserted into the upper third of the humerus (pectoralis major and latissimus dorsi). The long head of the triceps, together with its lateral and medial head, is inserted into the olecranon.

\* According to Codman, the quadruped uses his supraspinatus to accelerate a pendulum, while in man, in raising the arm, this muscle acts at a disadvantage against gravity and therefore under great strain.

† "Man has a relatively large and powerful acromion process to act as the mast of a derrick, to which his enormously developed deltoid is attached, and under which a relatively small supraspinatus is chiefly useful in holding the boom (humerus) on the fulcrum (the glenoid)."—Codman

Analysis of the origin and insertion of these two groups points to a system of muscles or levers controlling movements of the shoulder. The nature of these movements depends on their origins and insertions, or, in short, in which direction their forces are exerted. Contraction of the inner group limits mobility by pulling the head of the humerus toward the glenoid, their contractile force operating between their origin in the scapula and their insertion in the humerus. In the outer group traction is exerted mainly between the trunk and thorax and the upper third of the humerus, or, in the case of the long head of the triceps, between the glenoid and the olecranon. In order to understand the role of these muscles in the "frozen shoulder" one must visualize a system of forces operating from the spine, scapula, and thorax and pulling the humerus medially. On active or passive motion of the arm an opposing pull is exerted, but this is neutralized by the existing fibrosis and musculo-tendinous traction exerted in the opposite direction and tending to keep the shoulder in a position of flexion.

That the structures enumerated are involved in this condition has in part been borne out by a number of investigators. Perhaps the most convincing proof is study of the patient himself. On attempted extension, with the patient supine, both the latissimus dorsi and the pectoralis major stand out in relief, the latissimus dorsi laterally and the pectoralis major medially. The long head of the triceps may be felt in the axilla between these two muscular prominences as a hard, constricting band under the finger. Involvement of the inner group, excepting for the deltoid, is not as readily demonstrable. On attempted motion of the arm, however, it is found that both the scapula and the arm move as one due to contraction and fibrosis of the short rotators. I have also been able to prove involvement of these structures to my satisfaction by the repeated injection of procaine into the muscles or tendons themselves. This procedure, followed by manipulation, has frequently led to full use of the arm. Similarly convincing results have been obtained by the supraclavicular brachial plexus block.<sup>18</sup> In certain instances where the latter procedure was employed full motion was established immediately after injection. Such results were undoubtedly due to relaxation of spasm before the onset of fibrosis, however. When fibrosis had already been established adhesions were broken by gentle manipulation of the arm.

### Secondary Periarthritis (Periarthritis of Known Cause)

The causative factors underlying secondary periarthritis are more or less apparent and follow,

as a rule, a rather logical sequence of degeneration, trauma in the supraspinatus, formation of protective adhesions in and about the bursa, contraction and atrophy of the short rotators and of the outer group of muscles and tendons.

The starting lesion here is often in the tendon of the supraspinatus. A minor injury to already degenerated tissues, rupture of several of the fibers of the supraspinatus, often completely overlooked by the patient, may be sufficient to initiate the process of adhesions, protective spasm, and "frozen shoulder."

One of the better-known causes in this group is calcification of the supraspinatus tendon with rupture of the calcified deposit into the subacromial bursa. This initiates an inflammatory reaction in the bursa, which, by virtue of its power to form adhesions, becomes adherent to the surrounding structures. Pain induced by the bursitis results in spasm of the surrounding tendons. Inflammation, pain, spasm, and disuse finally lead to atrophy, fibrosis, and disability. Injury, which frequently precedes secondary periarthritis, may be valid and capable of inducing subsequent disability, or, as in primary periarthritis, may be insignificant in nature, and out of all proportion to the pain and subsequent discomfort which it arouses. In this latter instance, however, it is strongly suspected that a degenerative process, particularly in the supraspinatus tendon, precedes the somewhat inconsequential trauma.

Pinner and Staderman mention the work of Case and Carnett, who found in 26 cases that the sequence of changes in the tendon appeared to be first a primary interference with the blood supply, then ischemia and resultant necrosis. Calcium salts were later deposited in the necrotic tissue. In many instances, but not all, an inflammatory reaction was subsequently excited. This inflammatory reaction varied in degree from extensive formation of granulation tissue to the scattered infiltration of a few pus cells.

Codman,<sup>1</sup> who has opened many such shoulders, describes the stiffness and pain as due to the following changes in structures:

- 1 Adhesions between the roof and floor of the subacromial bursa involving (a) the subacromial portion, (b) the subdeltoid portion, and (c) the subcoracoid portion.

- 2 Adhesions between the bicipital groove and the tendon of the long head of the biceps.

- 3 Necrotic changes and inflammatory stiffening in the musculotendinous cuff.

- 4 Chronic inflammation in the synovial membrane of the joint and its capsule.

- 5 Adhesions in the extensions of the joint underlying the infraspinatus and subscapularis (subscapular and infraspinatus bursae).

FIG. 1. Injection—pectoralis major.

FIG. 2. Injection—latissimus dorsi.

6. Prolongation of the synovial lining of the joint down into the bicipital groove, the bursae under the infraspinatus and subscapularis, the subacromial bursa, and the glenoid half of the capsule.

It must be remembered that not all cases falling into this group present the above pathologic features in toto. Firm adhesions in one or more of the above structures might prove sufficiently valid to limit shoulder motion.

Codman<sup>1</sup> places the brunt of origin in traumatic cases on rupture of the fibers of the supraspinatus tendon; in the so-called spontaneous cases, on a necrosis of this tendon or even initial severe trauma.

It should be remembered that in spite of certain distinct causative factors already enumerated, the final clinicopathologic picture, with certain exceptions, may be indistinguishable from that of primary peri arthritis.

### Treatment of Periarthritis

Choice of therapy and subsequent response in primary and secondary peri arthritis once more point to an essential causative difference between these two forms in question.

In primary peri arthritis recovery is best obtained by a combination of local and systemic measures. In the secondary form ruptured tendon fibers must first be allowed to repair by rest, and mobility must be re-established by subsequent manipulation, heat, massage, and other measures. Complete rupture of the supraspinatus tendon is purely a surgical procedure which does not lead to peri arthritis<sup>1,2</sup> and therefore does not enter into this group of cases.<sup>1</sup> For peritendinitis calcarea before or during the onset of secondary peri arthritis a variety of therapeutic

procedures have been advocated: viz., long- and short-wave diathermy,<sup>19</sup> x-ray therapy,<sup>20</sup> surgical excision,<sup>1</sup> and needling<sup>21</sup> or irrigation of the subacromial bursa<sup>22</sup> when the deposit has already ruptured into the bursa. With proper treatment response in this latter condition is prompt, usually in a matter of weeks,<sup>1</sup> as compared to primary peri arthritis which, regardless of the therapy employed, is often long-drawn-out and tedious, and does not occur for months or even years.<sup>1</sup>

Treatment of the primary form encompasses a wide variety of therapeutic measures, including, for the debilitated patient, bed rest for a period of weeks.<sup>1,8,10</sup> Treatment of hormonal imbalance is effected with estrogens or thyroid extract.<sup>9</sup> Manipulation of the affected extremity, ranging from cautious stretching to full maneuverability under anesthesia, is also advised. Continuous stretching with traction apparatus appears to be the method choice with many.<sup>1,5,8</sup> Ultraviolet light, removal of focal infection, and other systemic measures are also advocated.<sup>9</sup>

Aside from the above systemic measures, based on pathology, a novel form of therapy is here proposed. This includes (1) injection of the specific structures involved followed by manipulation; (2) relief of pain and spasm by block anesthesia and subsequent stretching of the affected extremity.

### Injection of Specific Structures

The muscles and tendons injected by this technic are essentially the inner and outer group of structures outlined under "Pathology." The technic is simple and relatively free of hazards.

The patient is placed in a prone position, head flat on the table, and a small pillow is placed

FIG. 3. Long-head of triceps and point of injection.

FIG. 4. Injection—short rotators, patient on side.

under the affected shoulder to lessen pain during stretching. The arm is now passively extended until the contracted key structures stand out in relief. As already stated, the latissimus dorsi stands out laterally, the pectoralis major medially, and the long head of the triceps may be felt between these two at the midpoint of the axilla as a hard, constricting band. Strong pressure over these contracted structures usually elicits considerable pain. Three to 5 cc. of 2 per cent novocaine (procaine hydrochloride) are now injected into the belly of the muscles, and after a few minutes the extremity is firmly but cautiously extended with the forearm flexed on the arm. This is repeated several times. The long head of the triceps is similarly injected with 2 to 3 cc. of the solution, care being taken to avoid the axillary structures by repeated aspiration. At times the pectoralis major tendon is injected at or close to its insertion into the humerus when considerable tenderness exists in this area on palpation. Because of their role in pathology, the deltoid and teres major are similarly injected. Both tenderness and contraction, as demonstrable by palpation, act as a guide to injection. One or a number of the involved structures may be injected at one sitting, according to the condition of the patient. As a rule no more than two or three injections are given at one time.

The inner group of muscles are similarly injected with the patient in a sitting position, the arm passively extended to bring out contraction. The painful, affected structures may here be felt posteriorly as they offer resistance to the finger. Because of the frequent involvement of the under surface of the deltoid a more or less constant focus of pain corresponding to the upper third of the arm is also injected.

This technic, though necessitating patience

and repeated injection, especially in advanced cases, has, in my experience, led to good results and appreciably shortened the period of disability from one to one and a half years. Immediate mathematic proof of its efficacy has been demonstrated time and again by measuring extension before and after therapy. Suitable cases falling under the secondary group are treated similarly. Calcareous deposits, when present, are first dispersed when possible by injection of procaine into the deposit itself,<sup>19</sup> and the soft, mushy material is subsequently removed by needle irrigation. Incision and enucleation, however, is often the most direct method. See Figs. 1, 2, 3, and 4.

### Block Anesthesia and Manipulation

The efficacy of this form of therapy for the painful and disabled shoulder was demonstrated in 1937 by Steinbrocker and Tarsy.<sup>18</sup> Visual proof of its immediate efficacy in selected cases was offered by Tarsy<sup>23</sup> in the same year.

The brachial plexus on the affected side is first blocked through the supraclavicular route.<sup>18</sup> Injection is soon followed by paresis of the arm. During this phase of anesthesia the patient is unable to raise or otherwise use the affected extremity. In this state cautious manipulation is executed in the prone position. This method has distinct apparent advantages over manipulation with inhalation anesthesia. With proper technic, it is harmless, affords almost complete relaxation, though not as complete as with the former, and has the advantage of being sufficiently innocuous to be repeated a number of times, if necessary. Incomplete anesthesia gives poor results, however. Another advantage is the relief of periarticular and arm pain during and after anesthesia, followed by relief of spasm.

Block anesthesia and manipulation may be followed by a series of excellent measures advocated by Kendrick.<sup>8</sup> These measures, herein outlined, were, however, not employed by me in this series. Following manipulation:

Light traction should be applied to the arm, which is maintained in a position of 90 degrees abduction and 90 degrees external rotation.

During the first twenty-four to forty-eight hours ice caps are applied to the shoulder.

During the first two days following manipulation a complete range of motion is executed passively.

On the third day diathermy of low intensity is employed, followed by active movements of the arm.

On the fourth day active exercise of the arm by means of an "exerciser"\* attached to the head of the bed is instituted. This is followed by the reapplication of traction after each treatment. This traction should be used constantly during the first week.

At the end of one week the patient may be allowed out of bed for short periods.

During the final few days of treatment more active exercises are added, such as "wall-climbing" and placing the arm behind the head and back.

After ten days to two weeks the full range of motion is persistently maintained. Finally, the patient should be kept under close observation and physiotherapy and exercises should be continued until mobility and normal muscle tone are completely established.

When, for various reasons, the patient will not submit to block anesthesia and manipulation, and is content with a gradual improvement, the former technic of muscle injection and manipulation may be resorted to.

Thirty-four patients were treated by the above technics over a period of several years. Twenty-nine patients fell in the primary group and the remainder in the secondary group. All patients had previously received some form of therapy without improvement. Duration of disability in both groups ranged from two months to ten years, with an average of two and one half years. Twenty-seven patients obtained freedom from pain and complete mobility. Three were partially improved as to pain and function. In the remaining four patients treatment was totally unsuccessful. Duration of treatment varied from two weeks to one year, with an average of five months.

\* This consists of a length of rope running between two pulleys attached to the head of the bed about 2 1/2 feet apart. The ends of the rope are attached to two hand grips which are grasped by the patient and alternately worked downward. By this means the good arm helps to exercise the affected extremity.

When one realizes the therapeutic difficulties, the notoriously poor response to ordinary forms of therapy, and the long period of disability to which patients suffering from periarthritis are subjected, the above suggestions and technics appear to offer not only an innovation to the usual well-trodden therapeutic path, but also a practical system of shortening the period of disability.

## Summary

1. The similarity of one form of periarthritis of the shoulder joint to many phases of the rheumatic syndrome and the interest that it appears to present from a medical standpoint make it incumbent upon the medical man to have a workable understanding of this condition.

2. The main barriers to a clearer understanding of this condition in the past have been an insufficient knowledge of the causative factors involved as well as an incomplete understanding of its exact pathology. A synonymously repetitious and involved terminology as well as failure in many instances to distinguish between the two main forms of this condition have also led to considerable misunderstanding.

3. A more concise terminology of periarthritis, therefore, based on cause, pathology, and therapeutic response is herein proposed.

4. The causative factors, pathology, and clinical picture in the two forms of periarthritis in question have been set forth with particular emphasis on the specific anatomic structures involved.

5. Two forms of therapy have been employed for the treatment of this disability: (1) injection of the specific muscular and tendinous structures involved; (2) block anesthesia and manipulation.

6. A total of 34 patients were treated in accordance with the above technics over a period of several years. Of these, 27 patients obtained freedom from pain and complete mobility. Three patients were partially improved. In the remaining 4 patients treatment was totally unsuccessful.

7. The rather novel form of therapy here mentioned is introduced as an additional therapeutic approach, one which has led to comparatively prompt and satisfactory results in many hands.

## ARMY MEDICAL DEPARTMENT OBSERVES ANNIVERSARY

On July 27, the Army Medical Department observed the one hundred sixty ninth anniversary of the establishment of the first medical service for the American Army. The Medical Department had its inception in the creation by the Continental Congress, July 27, 1775, of a hospital for the American forces shortly after George Washington assumed command in the Revolutionary War.

Among the letters of commendation received by Maj Gen Norman T. Army, were ones from Commanding General and General Henry H. oral of

Gene  
sixty n.  
which

e hundred and  
Corps is one of  
and all the of-

ficers, nurses, and enlisted men of the Corps should be especially proud, and I hope that you will accept for them and for yourself my very sincere congratulations on a job most efficiently and bravely done.

"On the combat fronts and at home, you have seen, as I have, the superior performance of the Corps and have witnessed not only its splendid role in battle, but also its predominant part in recent medical development and experiment.

"The admirable execution of the mission of the Medical Corps has earned the complete confidence of the country in a function of the Army which is naturally closest to the civilian consciousness.

"We in the Army acknowledge and endorse that confidence, and in addition, add our personal congratulations and praise"—Release from the Office of the Surgeon General, Aug 8, 1944.

## COMMITTEE ON MEDICAL RESEARCH BEGINS PUBLICATION

The Committee on Medical Research of the Office of Scientific Research and Development, Office of the Surgeon General, has begun publication of a weekly journal entitled *Summary of Reports Received by the Committee on Medical Research*. Circulation of the publication is restricted to selec-

ted Medical Corps men in the United States Canada and Great Britain. The journal is edited and published by the Records Section of the Committee, under Dr Kenneth B Turner, assistant professor of Medicine, College of Physicians and Surgeons, Columbia University.

# PHYSIOPATHOLOGY, TREATMENT, AND PREVENTION OF FROST INJURIES

With Special Reference to Frost Injuries in Warfare

PAUL LIEBESNY, M.D., Bronx, New York

L T. GEN. J. C. EAKER, Commander of the Eighth United States Air Force, held his first formal press conference for American and British correspondents in London on March 24, 1943. General Eaker discussed in this conference a problem which is of great importance for physicians.

He pointed out that one of the phenomena which had proved troublesome for the Air Force was the occurrence of frostbite at the high altitudes at which the Flying Fortresses and Liberators operate. The difficulty is, he said, that the air crews are careless about adjusting their electrically heated clothing and persist in taking chances.

In the first World War we had to deal with frost injuries of the feet very often. The so-called trench foot occurred in soldiers who had to stay several hours or even days in trenches during positional warfare. In the war of movement the incidence of frostbite may be high, as we know from the Italian literature. In the Italo-French campaign of 1940 casualties due to frostbite were most numerous. The number was even higher in the armies of Germany and her satellites in the extremely cold winter of 1941-1942 on the Russian front, but there seem to be no details worth mentioning in the German literature. The occurrence of frostbite in the Russian Army is relatively low. This is to be expected, because the Russian people are accustomed to the cold climate and wear proper protective clothes, shoes, and gloves.

Trench foot was encountered in London in 1940 and 1941 among shelter dwellers and has been described by R. Greene.<sup>1</sup> This trench foot, called by Greene "shelter foot," was often seen among shelter dwellers who sat up all night with no compensating rest in a horizontal position during day. The occurrence of shelter foot was accelerated by the wooden bars of the deck chairs used by most of the patients. These wooden bars exerted prolonged pressure on the popliteal fossa, causing venous stagnation. Greene mentioned that the condition did not arise in wardens who, though exposed to the same degree of cold and damp, were frequently on their feet.

## Physiopathology

Frost injuries may be due to two causes: vasomotor disturbances or humoral pathologic changes.

*Vasomotor Disturbances.*—The normal physiologic reaction against exposure to cold is contraction of the small vessels and capillaries. The physiologic reaction becomes a pathologic state after longer exposure to intense cold, which does not have to be below 0 C., or after shorter exposure in real subzero temperatures.

The human skin, when exposed to low temperature, turns pale and by microscopic examination through the skin it can be seen that this is caused by the contraction of the capillaries, venules, and arterioles. After longer exposure the color changes to red, then to marble, and at last becomes cyanotic. This latter phenomenon is caused by the relaxation of the capillaries and venules. This relaxation, according to A. Krogh,<sup>2</sup> is a direct effect of the contractile elements which, due to local liberation of histamine or closely related substances ("H" substances) in the skin, become partly or even completely paralyzed. The constriction of the arterioles, however, persists. As long as this contraction is not extreme the skin remains red, but ultimately the constriction may become so extreme that no oxygen reaches the capillaries and the skin becomes cyanotic.

Proof that the local pallor in exposure to cold is caused by the contractile elements of the capillaries has been offered by Breslauer.<sup>3</sup> This author showed that this reaction may be elicited even in completely anesthetic regions. The further physiologic changes caused by cold are similar to those which Krogh could experimentally elicit on the tongues of frogs. This author dropped urethane on one single narrow capillary and arteriole of the mucous membrane of a frog's tongue. Whereas the arteriole remains narrow under the influence of urethane, the capillary dilates; more and more blood streams into the arterial part but not out of the venous part of the capillary. As a result the blood corpuscles agglutinate and form a clot in the venous end. Eventually the plasma with its colloids passes the capillary wall, causing edema in the interstices of the surrounding tissue. That is one cause of blisters in frostbite. If not enough

Director of the Physical Therapy Department of the Bronx Hospital, New York City.

capillaries remain intact for nutrition and oxygenization of the tissue, necrosis follows. The described reaction of the capillaries is a direct effect of cold or urticaria on the contractile elements of the capillaries, where is the vasoconstriction of the arterioles is of central origin.

Another reflex mechanism which may contribute especially to necrosis and gangrene of hands and feet may also be of central origin. That is the shunting of the arterial blood directly into the veins by arteriovenous anastomoses. These arteriovenous anastomoses were described by H. Hoyer<sup>4</sup> in 1887. More recently N. W. Popoff<sup>5</sup> has contributed very important studies on this subject. According to this author the arteriovenous anastomoses are seen almost exclusively on the ventral surfaces of hand and foot. T. Lewis and G. Pickering<sup>6</sup> proved that the arteriovenous anastomoses of hands and feet play an important role in the mechanism for regulating the general temperature of the body. However, this shunting of blood from the arteries directly into the veins with by passing of the capillaries may contribute to stasis in the capillaries.

### Humoral Pathologic Changes

The second cause for the occurrence of frostbite is humoral pathologic changes. These changes do not occur at temperatures above 0° Celsius but only below zero. They may occur at a lower degree below zero if the visomotor disturbances have already set in. At what degree of cold humoral pathologic changes in man may be inevitable cannot be told, but we may assume that temperatures below -20° C are always dangerous, especially for people who are not accustomed to exposure to such low temperature for a relatively long time.

The literature on humoral pathologic changes caused by exposure to cold in animals and man is inadequate. We have to rely on colloid chemical experiments and on botanical experiences. If a 2 per cent solution of gelatin is exposed to freezing temperature, ice crystals appear which gradually withdraw water from the gelatin. Eventually the water-poor gelatin forms a network which is enclosed in ice crystals. The same thing occurs in experiments with glue. By exposure to freezing temperature glue is changed to a spongy mass. The developed network persists even after thawing because the glue, through freezing, loses the ability to take up water in the same amount as before freezing. Also in plants the water leaves the cell and freezes on the wall.

that the surrounding tissue is torn to pieces. N. A. Maximow<sup>7</sup> discovered, furthermore, that

the developing ice not only accelerates the withdrawal of water but has also a mechanical coagulating effect upon the colloids of the protoplasm. It is important to keep in mind that also the living protoplasm of animals and man cannot sustain the loss of water to a higher degree. The molecular texture of protoplasm remains irreversibly destroyed if the loss of water transcends a higher degree. The loss of water in the plasma proteins is the second cause for the development of blisters, and the mechanical coagulating effect of ice crystals upon the colloids of the plasma may contribute to the agglutination of blood corpuscles and the formation of thrombi. The ice crystal formation and the loss of water in the plasma proteins explains the histologic findings in severe frost injuries, as there are the formation of vacuoles in the cells of the epidermis and subcutis and swelling out of interstitial tissue. In severest degrees of frost injuries the cutis, subcutis, cutaneous fat, and muscle are transformed into one mass with no structural differentiation. However, other histologic findings may be attributed to visomotor disturbances alone, e.g., the appearance of thrombi in the vessels and the sign of inflammation characterized by lymphocytic infiltration around the vessels. However, these lesions also may be accelerated or aggravated by ice crystal formation.

We may distinguish seven types of frostbite: (1) erythema and edema, (2) blisters and bullae, (3) superficial gangrene, (4) gangrene of skin and subcutaneous tissue, (5) gangrene of a whole part of an extremity or other parts of the body, especially the ears, (6) injury to muscles, tendons, periost, bone, and nerves without or with accompanying lesions of the skin, (7) chronic relapsing lesions of the skin—e.g., chilblains and other forms of erythrocyanosis.

The description of the pathologic anatomic findings of the different types of frostbite would transgress the aim of this paper.

### Treatment

*1. First Aid*—It is generally accepted that any kind of application of heat in frostbite is the worst thing that can be done. This is true in first aid as well as in treatment. Therefore, a patient suffering from acute frostbite should be brought into a cool room of about 58° F (10° C). The defrosting of the frozen parts must be done with great care by means of cool applications. As H. R. Clauston<sup>8</sup> stressed recently, the defrosting agent must have a temperature above freezing (32° F) and not above normal body temperature (98.6° F). Therefore, wet dressings with water of 41° F (5° C) to 58° F (10° C) have to be applied. The usually employed rubbing or

FIG 2 The same patient cured and discharged  
after four short-wave treatments February 20, 1943.

massaging of the frozen parts should be avoided. It may be harmful, causing injuries to the skin. The application of external heat to the frozen parts in turn is harmful because it increases locally the metabolism of the tissues. The blood supply which may be sufficient at low temperature of the tissue may become insufficient when the temperature is increased artificially. Therefore, the development of necrosis may be stimulated by heat. This is already known to be true in frostbite caused by vascular disturbances alone. Whether or not rapid thawing of actually frozen tissue increases the damage caused by the described humoral pathologic changes cannot be decided. The experiments on plants show that most of the plants may survive upon rapid or slow thawing after being frozen. However, there are exceptions; e.g., some types of pears and apples and the leaves of *Agave americana* always die after rapid thawing, whereas they survive after slow thawing.

There is, however, no doubt that rapid thawing in man stimulates the deleterious effects of the circulatory disturbances. In their important paper on "Refrigeration Anesthesia," L. W. Crossman<sup>9</sup> and his collaborators showed that

various degrees of elevation of temperature within febrile range enormously accelerate gangrene in bloodless limbs.

2. *Refrigeration Therapy.*—F. M. Allen, L. W. Crossman, and F. K. Safford<sup>10</sup> have treated with refrigeration a patient suffering from second-degree frostbite on both hands. One hand was put into an electric refrigerating box at 50 F.; the other was placed upon a bare icebag. After one week the hands were gradually restored to normal temperature. Healing was complete with "far less tissue loss than had been anticipated and with no residual complaints except some reduction of touch sensation."

The treatment of frostbite by refrigeration was recommended first by S. Stiassny,<sup>11</sup> an Austrian military surgeon, in 1904. This author treated frostbite with a spray of ethyl chloride. The therapeutic effect of refrigeration in frostbite may be explained partly by its antiphlogistic effect. On the other hand, this kind of treatment permits only a very gradual increase in the temperature of the frozen parts up to normal body temperature, so that there is sufficient time for the improvement of circulation by itself.

We may, however, not expect an active increase

and improvement of the circulation by refrigeration therapy of frostbite. To achieve this active improvement two methods have to be considered: (1) short-wave application at low intensity, and (2) sympathetic anesthesia and sympathectomy.

3. *Short-Wave Therapy*.—Short-wave therapy of frostbite, even in cases of gangrene of the extremities, is effective, according to my experience and according to recent publications of Italian authors. The short-wave current is applied with air-spaced electrodes. The treatments are given daily for ten minutes. The current is applied in such a dosage and the electrodes are kept at such a distance that the increase of the temperature of the skin in the treated area does not exceed 0.5 Celsius after ten minutes of application. I had reported in 1935<sup>12</sup> the short-wave treatment of 45 patients suffering from gangrene of the extremities of different causation, including frost injuries. Twenty-one of these patients were cured, 8 were relieved, one suffered a relapse after a short time, and 15 did not respond. Most of the patients who did not respond were suffering from diabetic gangrene. The average number of treatments given in gangrene cases was thirty. The highest number of treatments was given to a patient 65 years of age, suffering from arteriosclerotic gangrene of the left foot. The patient was cured after seventy-four treatments. This patient died four years later of pneumonia.

In frostbite of first or second degree complete recovery is usually accomplished in very few treatments. We had the opportunity in New York City in the winter of 1942-1943 to treat 4 patients with frostbite. All of them acquired the frostbite on February 15, the coldest day of that winter, with the lowest temperature of -8 F. (-22 C.) at 8:30 A.M. All 4 patients recovered completely after two to four treatments. Fig. 1 shows one of these patients suffering from second degree frostbite of the left ear before starting the treatment on February 15. Fig. 2 shows the patient after four treatments, on February 20.

Recently L. Borini and G. Matli<sup>13</sup> and P. Cignolini<sup>14</sup> reported favorable results in treatment of frost injuries with short-wave therapy in dosage of low intensity. Cignolini, for example, writes that his patients have no sensation of heat for the first six to eight minutes of treatment and feel a slight warmth between the eighth and tenth minutes. Cignolini found that even in patients admitted with dry gangrene only the mummified part was lost, while other segments were saved, regardless of their condition on admission. Referring to the technic of Cignolini, I have to warn against relying upon the subjective sensation of warmth of the patients in short-wave treatment of frostbite. I found<sup>15</sup> in ex-

perimental examinations on patients who were not suffering from disturbances of temperature sensation that there is no true relationship between the degree of the temperature increase of the tissue and sensation of temperature. At present the only way to avoid an overdosage is by measuring the skin temperature with a thermocouple in order to learn which dosage of current of the short-wave machine at our disposal has to be applied to achieve the desired result.

4. *Sympathetic Anesthesia and Sympathectomy*.—R. Lerich and J. Kuulin<sup>16</sup> recommend anesthetic infiltration of the lumbar and stellate sympathetic in patients suffering from frostbite with edema and pain. Nearly all patients were immediately relieved. The infiltrations were repeated on the following two days. It was found, if there was no necrosis or infarction, that all patients were well in a few days. J. de Girardier<sup>17</sup> recommends injections of the lumbar sympathetic with procaine hydrochloric (10 cc. of a 1 per cent solution) in frostbite of the feet without necrotic lesions. The author found that five infiltrations at intervals of two or three days are generally sufficient. Periarterial sympathectomy is indicated, according to Girardier, in necrotic ulceration, whereas he limits himself to section of the lumbar chain with ganglionectomy in cases with pronounced bilateral circulatory disturbances with or without necrotic ulcerations. This author also regards interventions on the sympathetic as a great advance in the treatment of frostbite lesions *without massive gangrene*. There is no doubt that the above-named methods are of definite value in producing vasodilatation and will improve the circulation in frostbite and achieve healing. But it is my belief that at least the same results can be obtained by short-wave therapy, which method is certainly superior in frostbite with gangrene. Frank V. Theis,<sup>18</sup> in a very important study on frostbite, refuses to submit patients to the hazards of an operation when satisfactory results can be obtained by conservative measures. This author recommends paxev treatment in frostbite.

5. *Plasma Transfusion*.—There is no doubt that all methods which improve the circulation will contribute to the healing of frostbite even if a small part of the affected tissue were actually frozen with ice crystal formation. However, if a larger part of tissue—e.g., a whole leg—were affected in this way the damage would be irreparable if we did not try to overcome the loss of plasma into blisters or damaged tissues and try to replace deranged plasma.

I should like to suggest consideration of transfusions of undiluted plasma in patients who are suffering from frostbite of large areas and of high degree. In order to be effective it is probable

that these transfusions should be given during the first twenty-four hours. It is also probable that this method might save extremities which otherwise would be lost.

### Prevention of Frost Injuries

The problem of prevention of frost injuries is of special importance in warfare. This problem includes protective clothing, adaptation to cold, proper nutrition, and the knowledge of predisposition to frostbite. I shall discuss here only the protective clothing of flying personnel and the predisposition to frostbite.

1. *Protective Clothing of Flying Personnel.*—The problem of protective clothing against frost injuries is especially difficult for flying personnel. The temperature decreases in general about 2 C. or 3.5 F. for each 1,000 feet of ascent. Therefore the drop in temperature between sea level and 20,000 feet will be 70 F. and between sea level and 35,000 feet about 122 F. This is untrue only in the arctic area in wintertime, where temperatures a few thousand feet off the ground may be higher than at ground level.

Flying personnel begin to suffer from cold, according to H. G. Armstrong,<sup>19</sup> at temperatures below 10 F. or -12 C., i.e., at about 13,500 feet above sea level, in spite of winter flying clothing. At first there are chilly sensations, accompanied by increased metabolism and muscular restlessness. The chilly sensations change to discomfort and the acuity of touch sensations and muscular reactions is dulled. The muscles may assume a state of mild tonic contraction, which further hampers and restricts free movement. Discomfort changes to pain, general shivering follows, and voluntary muscular movements become sluggish. There is no doubt that the best solution of the problem of protecting flying personnel against the rapid changes of temperature and atmospheric pressure will be a pressure-sealed cabin where artificial pressure and heat give the proper protection. But this kind of airplane is still an exception. In open-cockpit airplanes we have to rely on protection by proper clothing. Very heavy clothing is necessary to maintain heat balance at high altitudes. However, the weight and bulkiness of such clothing hampers the activity of the personnel, as described recently by E. A. Pinson and O. O. Benson.<sup>20</sup> To reduce this bulkiness, electrically heated clothing is now in general use. A disadvantage of electrically heated suits, as Pinson and Benson stressed, may be that the physiologic mechanism normally responsible for heat balance in the body will be upset by this mode of external heat application. If, for example, a flyer starts to heat his clothing at about 5,000

feet (at about 5 C. or 41 F.) his arterioles and capillaries may dilate and profuse sweating and all the discomfort of overheating may occur. This will hinder the flyer's making the proper adjustment to the environmental temperature and induce him to diminish the heat supply or even to stop it just at the time when an increase of heat would be necessary. The loss of body heat now will become much greater because the arterioles and capillaries are in a stage of dilation and some of the physiologic adjustment to cold—e.g., the increased adrenalin output, with consequent constriction of the arterioles, may be delayed. This can stimulate the development of frost injuries. I think, therefore, that carelessness of the air crew is not the reason for incorrect adjustment of their electrically heated clothing. There is no possibility for them to rely upon the sensation of comfort or discomfort due to heat or cold. They are quite unable to adjust properly the supply of heat needed in proportion to the decrease in the environmental temperature during ascent and the increase during descent.

I have drafted an instrument which may accomplish the automatic regulation of the heat supply in flying suits proportionally to the altitude at which the airplane happens to travel. The importance of properly regulated electrically heated clothing, especially the importance of avoiding overheating, may be illustrated by an experience of the French physiologist and physiotherapist, Stephan Leduc.<sup>21</sup> This author observed severe chilblains in patients who in wintertime had the habit of heating their extremities with electric thermophores, infrared lamps, or by exposure to hot iron stoves. The chilblains of these patients responded to treatment only after the patients gave up the habit of heating their extremities in these ways. This experience of Leduc may also explain the frequent incidence of frostbite of flying personnel using electrically heated suits.

2. *Predisposition to Frostbite.*—L. Brahamy<sup>22</sup> observed 338 cases of frostbite which occurred among employees of the Sanitation Department of the City of New York during the winter of 1933-1934. He found an increased susceptibility to frostbite in people suffering from vascular diseases or diabetes. People suffering from diabetes or manifest vascular diseases will certainly not be taken into the Army. However, there are some otherwise healthy people who exhibit a bad vasomotor reaction to cold. The simplest way to discover this vasomotor disturbance is as follows: after application of any kind of cool-water procedures the skin of a person with a normal vasomotor reaction turns red and a sensation of comfortable warmth then appears quickly. People with an abnormal reaction remain pale or

even get cyanotic for a considerable time and the sensation of cold and shivering sets in too. There is no doubt that people with this kind of vasomotor reaction to cold are especially susceptible to frostbite. This abnormal vasomotor reaction may be overcome by methods of adaptation to cold, otherwise, these people must not be exposed to subzero temperatures for a long period of time. Furthermore, patients suffering from thrombo-angitis obliterans, or Buerger's disease, are certainly predisposed to frostbite gangrene. Buerger's disease occurs in young adults and is usually overlooked in the acute stage. These patients start to suffer usually only when the disease enters the chronic stage after it has been in progress for months or even years. Even in the acute stage, however, any insult—e.g., exposure to cold—may aggravate the already present but not recognized circulatory disturbance to such an extent that gangrene of the extremities may follow.

I had the opportunity of treating two white men, 25 and 28 years of age, respectively, who were suffering from gangrene of the feet after sking. It is unusual for healthy adults to acquire frostbite while sking. Further observation proved that both patients were suffering from Buerger's disease, despite the fact that they had no reason to complain before "the accident of freezing." According to all we know about thrombo-angitis obliterans, we cannot assume that in these or in similar cases the exposure to cold caused the disease, but that the development of frostbite gangrene was stimulated by the already present pathologic changes of the vessels.

A very important study of F. V. Theis and M. R. Freeland<sup>23</sup> dealt with the problem of the early diagnosis of Buerger's disease. They found in a series of 7 cases of acute thrombo-angitis obliterans increased viscosity of the venous blood, rapid coagulation, and arterial oxygen saturation. Whether or not the findings of Theis and Freeland may be accepted can only be decided by examination of a greater number of cases. The number of men inducted into the Army despite the fact that they are suffering from unrecognized thrombo-angitis obliterans is certainly very small. However, if persons suffering from this disease are exposed to cold the development of frostbite gangrene may be expected. Examinations which could lead to an early diagnosis of Buerger's disease in the acute stage should, therefore, not be omitted.

## Summary

The most frequent forms of frost injuries in warfare are trench foot, "shelter foot," and frostbite, especially of flying personnel.

by exposure to low temperature above 0°C or by humoral pathologic changes which may occur in consequence of actual freezing of the body fluids on exposure to subzero temperature.

**Treatment**—1 Every kind of application of heat is harmful. In first aid the defrosting of frozen parts must be done by means of cool applications. Wet dressings with water of 41 to 58°F have to be applied. Rubbing or massaging of the frozen parts should be avoided.

2 Refrigeration therapy, according to F. M. Allen and collaborators, may be tried.

3 Short-wave therapy at low intensity has been found effective by this author and by Italian clinicians.

4 The pros and cons of sympathetic mesotherapy and sympathectomy have been discussed.

5 The author suggests consideration of early plasma transfusion in patients who are suffering from frost injuries of large extent and high degree.

**Prevention**—1 Protective clothing for flying personnel has been discussed. Electrically heated suits may be the best solution of this problem, but it seems necessary that the supply of heat should be automatically regulated in proportion to the altitude reached by the airplane.

2 Predisposition to Frost Injuries. Individuals with an unrecognized abnormal reaction to cold or those suffering from thrombo-angitis obliterans in the acute stage may be predisposed to frost injuries.

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the November 1 issue and will concern "Management of Abdominal Distention."

### Treatment of Drug Addiction

DR. HAROLD G. WOLFF: We are going to discuss today the management of morphine addiction. Dr. Wikler, who is a member of the U.S. Public Health Service, and who works at the Narcotic Farm in Lexington, Kentucky, where such patients are cared for, has had wide experience with these patients and will epitomize the problem for us, and allow us to bombard him with questions. Dr. Wikler.

DR. ABRAHAM WIKLER: While I shall try to limit the opening of this discussion to the treatment of drug addiction, I think it is necessary to state first what the general problem is so that the rationale of the treatment may be better understood. In this discussion I shall consider only addiction to opiates. There are other important "drug addictions," such as to alcohol and the barbiturates, but since my experience has been limited almost entirely to opiate addiction, I shall discuss this phase of the problem alone.

Drug addiction presents a problem in psychosomatic (or somatopsychic) medicine. We have to deal with a derangement of the entire personality, including both its physical and its mental aspects. Treatment must be directed toward all of the basic factors involved in drug addiction. If it is directed solely to one or another aspect of the problem, treatment will be futile. In the treatment of opiate addiction we have to consider the phenomena of tolerance and physical dependence. These usually go together, although in the case of other drugs tolerance can occur without physical dependence. In addition to tolerance and physical dependence we have to deal with habituation or "psychic dependence," which is manifested by the tendency for the patient to relapse to the use of opiates even after he is no longer physically dependent on the drug. When we speak of drug addiction to opiates we include all three of these concepts, and it is therefore apparent that one cannot treat physical dependence alone or habituation alone and expect satisfactory results.

At Lexington there has been evolved a program for the treatment of the patient from this point of

view—that is, treatment of the organism as a whole. Detailed reports concerning this treatment have been published from time to time, particularly by Dr. Lawrence Kolb, Chief of the Mental Hygiene Division, U.S. Public Health Service, Dr. Ossenfort, Dr. J. D. Reichard, Medical Officer in Charge, Dr. C. K. Himmelsbach, Director of Research, Dr. M. J. Pescor, Dr. R. H. Felix, and their associates at the U.S. Public Health Service Hospital, Lexington, Kentucky. The treatment of drug addicts in that institution as it is today is the result of the combined efforts and research of this group.

The treatment consists essentially of withdrawal of the drug and rehabilitation of the patient physically, psychologically, and sociologically. To this end the institution at Lexington admits patients of several categories. We have a volunteer group. These are patients who ask for admission after they have been certified as drug addicts by their physicians and have completed the necessary forms, which are obtainable from the Surgeon General, U.S. Public Health Service, Bethesda, Maryland. These patients are admitted free of charge if they cannot pay; if they can they pay, a dollar a day. The largest group, however, consists of patients who are sent to the institution for violation of some Federal statute, and these are divided into several groups. Most of them have prison sentences to serve. If they are addicts and in need of treatment, they are sent to Lexington. Another group consists of "probationer" patients who have been arrested for violation of the Harrison Narcotic Act but whose sentences have been suspended upon the promise that they will report to the hospital for treatment and remain there until they are pronounced cured by the medical staff. After arrival at the hospital these patients are all treated alike from the medical standpoint. However, some differences in the custodial regulations do arise because of differences in their legal status.

On arrival the patient is taken to the admission room, and the first physical examination, which

is brief but careful, is given there. After it has been determined that the patient has brought in no contraband, he is examined for gross physical defects, cardiac, pulmonary, or nervous disorders, and contagious diseases. Particular attention is also paid to evidence of active physical dependence on the drug. This is not a simple procedure. There is no way of proving that a patient is dependent on morphine except by watching for withdrawal signs which appear in such patients when morphine is withheld. These appear within thirty hours or less from the time of the last dose. If for some reason, medical, legal, or other, one wishes to demonstrate that a patient is physically addicted to opiates, he must be studied in a controlled environment under constant observation for a day or two, and only if the characteristic withdrawal signs appear can one state that the patient is physically dependent on the drug. We do not usually have to subject the patient to this procedure at the time of his arrival, but we do try to observe other, though less conclusive, signs of active addiction.

Of these, constriction of the pupils is probably the most significant. This may be present if the patient has had morphine recently—that is, within several hours before admission to the institution. There may also be some degree of stupor or other evidence of the narcotic effects of the drug. We also look for fresh needle marks. These may be the result of subcutaneous injection, in which case they usually appear on the lateral aspects of the arm or the thigh, or of intravenous injections, in which case pigmented scars may be seen in the antecubital fossae or elsewhere. A brief history is taken with particular reference to addiction—namely, the time of onset of addiction, the average daily dose, the reasons for relapse, and the reasons given by the patient for the use of drugs in the beginning.

If, in the opinion of the examining physician, the patient is actively addicted to the drug, he is sent to the withdrawal ward. The procedure there is, first of all, to make the patient comfortable. Withdrawal is not begun immediately, but the patient is given enough morphine to achieve "stabilization." The exact amount given varies from case to case and depends to a large extent on the quantity of morphine habitually taken by the patient, and on the signs exhibited by him after delaying injection of morphine for about twelve hours. Ordinarily  $\frac{1}{2}$  gram of morphine every four hours or 1 gram every six hours will suffice. If, from the available evidence, the examining physician finds that physical dependence is not very strong he may start with  $\frac{1}{8}$  or  $\frac{1}{4}$  gram of morphine every six hours. In rare cases with very mild physical dependence, morphine may be withdrawn imme-

diately. The object of this preliminary stabilization is to get the patient used to the surroundings of the hospital, to show him that he is not going to be treated by the well-known "cold turkey" method, which consists of nothing but abrupt withdrawal, and also to "size the patient up," with reference to his personality and physical condition. After two or three days of stabilization, during which a more thorough physical examination is made and the patient, the doctor, and the hospital staff have become acquainted with each other, withdrawal is begun.

The method used at Lexington is that of rapid reduction. The doses of morphine are progressively reduced in size so that by the end of a week or ten days the patient is receiving no opiates at all. The exact procedure varies with the individual case, and several methods have been proposed. Dr. Himmelsbach prefers to space the injections nineteen hours apart. The initial or stabilization dose is cut in half, and then at the time of the subsequent dose, half the preceding dose is given, and so on until the patient is down to about  $\frac{1}{8}$  grain of morphine. After that, codeine is substituted, and a day or two later all opiates are discontinued. The rapidity and the method of withdrawal depend to a large degree on the abstinence signs which the patient exhibits during the course of withdrawal. Since these are very important and are the foundation for the treatment of the withdrawal phase of morphine addiction, I will go into them in some detail.

A method has been devised by Dr. Himmelsbach for evaluating objectively the signs which the patient exhibits on withdrawal of morphine. For quantification, the signs are scored in terms of points. The first group consists of yawning, lacrimation, running of the nose, and sweating, to each of which is assigned one point. The next group consists of anorexia, mydriasis, tremor, and goose-flesh. The third consists of restlessness, emesis, elevation of temperature and blood pressure, and loss of weight. In practice, the patient is observed in bed or in a special examining room every few hours and the scores are recorded on a special card. In this way at the end of the day one can add up the total number of points and arrive at an objective estimate of the intensity of the abstinence syndrome. There is another phase of the problem, however—namely, the reaction of the patient as a whole to the discomfort which accompanies the exhibition of these signs. The nature of these secondary reactions is determined by the adaptive mechanisms of the individual case and therefore is as diverse as the personalities of addicts themselves.

As you know, many so-called treatments of the morphine-abstinence syndrome have been pro-

drinking makes it expedient to place them in a single category.

Psychoses due to opiates or opiate addiction per se are said to exist, but no such case has ever been seen at Lexington. Psychotic patients are admitted with active "habits" but their psychoses antedate or are unrelated to addiction. In these cases, paranoid schizophrenia probably constitutes the largest single group.

After the patient is in condition to do so he is brought before a classification board, where all the facts I have mentioned are considered, and the patient is assigned to a suitable department of the institution for further treatment. He may be recommended for special psychotherapy or may be treated routinely. He is assigned to a definite occupation on the farm, in the industries, maintenance shops, or hospital, and he is given vocational training if necessary. In the time available, which we think must be at least six months in the average case, an attempt is made to correct, as far as possible, basic personality difficulties which predispose the patient to relapse. Each patient is assigned to a psychiatrist who administers psychotherapy as indicated and who interviews all patients under his care from time to time to follow their progress. The patient's general health is cared for by daily clinics, or "sick calls," as they are termed, and the facilities of a complete general hospital within the institution are available to him at all times. He may also avail himself of diversified educational and recreational facilities. After a period of about six months the patient is considered for discharge by the medical staff, provided this is consonant with the sentence, if any, which he has to serve. The criterion for discharge as cured is whether or not the patient has acquired the power for self-control with reference to the use of narcotic, habit-forming drugs as defined by law. If discharge is recommended, efforts at occupational placement and follow-up studies are made by the social service department.

This, in a general way, suffices for a description of the treatment of drug addicts at the U.S. Public Health Service Hospital at Lexington, Kentucky. Now we can take up any special aspects of the problem which you may wish to inquire about.

DR. WOLFF: I wonder if you could let us have the percentage of cures in the various groups.

DR. WIKLER: The percentage of cures has not been broken down with respect to each of the groups in Dr. Kolb's classification. In general it is difficult to state when a patient is actually cured. By "cure" we mean that a patient not only is not physically dependent upon but does not relapse to the use of drugs. Because of legal complications and other administrative diffi-

culties, our follow-up system is not wholly satisfactory, but a very conservative estimate is that about 12 per cent of the patients that are treated are actually cured. There is a large group of patients whom we lose track of after they leave the institution; it is reasonable to assume that a considerable percentage of these remain "cured." However, 35 per cent of those treated are known definitely to relapse. As for the 12 per cent that are actually cured, I know of no study regarding their distribution in the Kolb classification. From my own personal experience I would say that our cures are obtained chiefly from the second group and the occasional patient in the first group.

DR. HARRY GOLD: The so-called cure—that is, having the patient leave the hospital without symptoms and without drug—applies to 100 per cent of those cases, does it not?

DR. WIKLER: We do not call that a cure. If the patient leaves the hospital he obviously has been cured in the sense that he is no longer physically dependent upon the drug, but if he relapses as soon as he steps outside the gate, we cannot consider that he has been cured.

DR. HARRY GOLD: That takes how long on the average?

DR. WIKLER: We feel that about six months is required. Studies on the physical condition of those patients with respect to the effects of the drug seem to indicate that after the withdrawal of opiates the patient is not free from the effects of addiction for about six months; that is, taking a large number of patients who have been "withdrawn" and studying them through withdrawal, convalescence, and recovery, we find there are small differences up to six months after withdrawal. We try to keep them about that length of time. Voluntary patients can "sign out" when they want to, but probationer patients who leave against medical advice may forfeit the suspension of their sentences and be rearrested and returned as prisoners. In many instances patients have been discharged as cured after shorter periods of treatment. We have discharged voluntary patients as cured within three or four months and have done so in a few instances with probationers.

DR. GOLD: I want to amplify my question. How long does it take before the patient can get on without morphine in the hospital? He might stay in the hospital very much longer, but from the beginning of the reduction to the time when no more drug is needed, how long is the average time?

DR. WIKLER: I should say about ten days.

DR. WOLFF: Dr. Wikler, if you were living in a small city and you discovered that one of your patients was addicted to an opiate, how would you manage that man's problem? Would you

treat him, or how would you proceed? Most of us are going to be doing a different kind of practice from the one you outlined. Is it possible to treat a drug addict under circumstances other than those you described?

DR. WIKLER: I believe it is possible to treat drug addicts who fall into the first group, normal individuals, people with personalities not very different from the average, whose adjustments have heretofore been satisfactory and whose addiction to opiates has been purely accidental, the consequence of some illness or other condition over which they had no control. Such patients may be treated by the private physician. But patients with personalities corresponding to those of the other groups in the classification we use probably cannot be treated satisfactorily outside of an institution.

DR. WOLFF: You recommend that they go to a psychopathic hospital or some place where they are restrained during the period of withdrawal?

DR. WIKLER: Yes, I would say that they should go to an institution where some control over their treatment is exercised. That is, where they can be kept for a sufficient length of time to effect a cure.

DR. WOLFF: Suppose you were attending at a large hospital, for example, and a patient with rheumatic fever were discovered to be an addict, would you undertake the treatment while the patient was on the ward?

DR. WIKLER: If his physical condition permitted it, I think that one could undertake withdrawal of the drug. The chances of permanent success would depend largely upon the personality of the patient. If the chief addicting factor was rheumatic fever, the chance of success would be good. If, on the other hand, the addiction was based upon the relief of tension which the patient experienced when the drug was administered, and the tension was based on personality difficulties of a serious nature, I would think that treatment would not be successful in a short time.

DR. WOLFF: As you describe these effects of physical dependence, it sounds as though they might be the bodily manifestations of terror or panic, or desperation. Is it possible that they are merely the outward signs of the individual's distress at having this important agent withdrawn; and, if one were to give the patient reassurance and spiritual support he might not need the drug during that period?

DR. WIKLER: I do not think so. I believe that these signs of withdrawal are intimately linked up with the patient's development of physical dependence upon the drug. They may be aggravated or perhaps diminished by the reaction of the patients to these symptoms, but there is a lot of evidence to indicate that they are not merely

the effects of anxiety. In the first place, one can see marked signs of physical dependence in patients who, at least externally, show little or no anxiety, and go through this period calmly. On the other hand, patients who express great anxiety and are obviously terrorized by the prospect of withdrawal may exhibit none of these symptoms if their addiction is mild. Furthermore, the symptoms and signs observed in addicted animals, such as the dog, the monkey, and especially the chimpanzee, are similar to those seen in human beings. The progression of these symptoms is almost identical, too. Moreover, the failure of hypnosis, barbiturates, and the lowering of body temperature to influence the abstinence signs significantly suggest that they are not merely the manifestations of experienced anxiety or terror.

DR. McKEEN CATTELL: Do you have any criteria for determining which of the withdrawal symptoms are entirely psychologic?

DR. WIKLER: It is my opinion that, since the autonomic nervous system can respond only in certain fairly circumscribed ways to stimuli of any sort, such as withdrawal of a drug on which neurones have become dependent or in the process of adaptation to an unpleasant situation, it is impossible to say which particular abstinence sign is "psychologic" and which is not. However, in the abstinence syndrome there is a fairly uniform sequence of events, which indicates that they are not entirely dependent upon the mental reaction of the patient. The early symptoms, yawning and lacrimation, for example, are not characteristic of anxiety states; yet they appear almost constantly during withdrawal. On the other hand, patients with anxiety may show very marked mydriasis without such characteristic withdrawal signs as piloerection or rhinorrhea.

DR. WOLFF: I notice that you build up the patients after withdrawal. Is there any advantage in building them up and then withdrawing?

DR. WIKLER: If the patient's condition is very bad we try to build him up first and then withdraw, but in the average case we do not feel that there is much to be gained by building the patient up from a marginal level to a very good one before withdrawing.

DR. WOLFF: I understand there are important fluctuations in the weight curve before and after withdrawal. Will you comment on that?

DR. WIKLER: During the period of abstinence there is quite a drop in the curve, which gradually rises again after withdrawal is completed.

DR. WOLFF: Is there an average drop of about 3 kilograms?

DR. WIKLER: About that; 3 or 4 kilograms during withdrawal.

DR. WOLFF: Is the patient eating well during that period?

DR. WIKLER: The curves of weight and caloric intake are in general parallel during the first five days after withdrawal. Later they diverge.

DR. WOLFF: Is there a period of hydration during which the patients gain weight from the fluid intake?

DR. WIKLER: Yes. Addiction is accompanied by hydration, as studies by Dr. Williams have shown.

DR. GOLD: I take it, from all that you have said, that physical dependence is of little importance in the larger problem of controlling morphine addiction. The symptoms of physical dependence may be cured in ten days or so. Psychic dependence or habituation seems to be the aspect of addiction so resistant to cure. Do you agree?

DR. WIKLER: Most important is the role of personality in the development of addiction. That question has been discussed by many people, and there is no general agreement, but it appears to many observers, and Drs. Kolb and Himmelsbach have so stated, that the basic problem is one of personality defect. But we do know this: that people who have so-called inadequate personalities find it more difficult to discontinue use of the drug once physical dependence has been established, because of the discomfort attending withdrawal. They therefore continue to use it even when they no longer obtain the "lift" or feeling of euphoria for which they took it in the first place. The economic, social, and personal consequences are disastrous. For these reasons the development of physical dependence must be considered an important phase of the problem of drug addiction.

INTERN: What is your attitude toward the use of insulin in these cases?

DR. WIKLER: I have had no experience with that personally, but Drs. Kolb and Himmelsbach state that it is of no value in the treatment of withdrawal symptoms. We sometimes use insulin in 15-unit doses several times a day to improve appetite and promote the ingestion of food during the period of fall in the caloric intake curve. We find that that is of some value in maintaining the weight of the patient during withdrawal.

DR. CATTELL: Have you had any experience with marihuana in relation to morphine addiction?

DR. WIKLER: I have never tried it, but it has been tried in the treatment of the morphine abstinence syndrome at our hospital and found to be of no value.

INTERN: In connection with the supposedly harmful effects of morphine addiction in China

and elsewhere, how does one account for the fact that some people go on as addicts for many years apparently without damage to themselves?

DR. WIKLER: Your question might be phrased: Does morphine prove deleterious in and of itself?

DR. WOLFF: Along the same line, can an addict continue on the same dose and be effective in his work?

DR. WIKLER: Apparently that can be done, but only rarely. To achieve "equilibrium" the addict is constantly preoccupied with getting enough or injecting enough but not too much of the drug to prevent withdrawal symptoms. It is hardly likely that in the face of such a problem the addict can fulfill the responsibilities and obligations that are incumbent on members of society. One cannot have a chronic disease like morphinism, which requires constant "treatment," and be up to par any more than one can have chronic arthritis and work at top efficiency. Conceivably, an occasional addict may make a reasonable adjustment during addiction, but this is rare.

DR. C. H. WHEELER: If morphine were cheap and as easy to buy as cigarettes, would that difficulty exist?

DR. WIKLER: Of course, if morphine were easily obtainable, the social and economic problems complicating the lives of addicts would be solved to a large extent, and some of them might become reasonably useful citizens. However, this would not solve the over-all problem of morphine addiction, for several reasons. First, the addict is rarely able to achieve physiologic equilibrium even if he has a plentiful supply of morphine. This is difficult to do even on a research ward. Second, "normal" behavior is achieved only when the goal of personal satisfaction, which we all seek, is reached by activity determined by drives which have social value, such as security, prestige, family attachments, financial independence, etc. When personal satisfaction can be acquired through the simple expedient of injecting morphine these activities are rendered superfluous and the addict becomes a useless burden on his family and society in general. Third, easy availability of such a potent sedative as morphine would lead to its use by thousands, perhaps hundreds of thousands of neurotic, psychopathic, or otherwise inadequate people, of whom there are plenty in any society. A somewhat similar condition actually prevailed in this country before enactment of the Harrison Narcotic Act, and in Germany just after the first World War.

### Summary

DR. WIKLER: Treatment of drug addiction must be directed toward both physical and

psychic dependence. For the former, rapid reduction is the method of choice, morphine being the only "specific" drug used. Supportive therapy, such as infusions of glucose in saline, warm baths, massage, bromides and barbiturates, vitamins, and high caloric diets are also employed. In the presence of cardiac failure, acute infectious disease, far-advanced active tuberculosis, tabetic crises, and other acutely painful conditions, withdrawal is delayed until the acute condition is relieved. Habituation (psychic dependence) is treated by such measures as are indicated after thoroughgoing physical, psycho-

metric, and psychiatric studies are made. Such treatment is best carried out in a suitably equipped hospital over a period of about six months. The prognosis depends largely on the underlying personality. The best results are obtained in these patients whose adjustment in life had been fair until addiction. The relative importance of the abstinence syndrome in addiction and the need for rigid control of the dispensing of opiates are discussed.\*

\*Dr. Wikler wishes to express his thanks to Dr. C. K. Himmelsbach for the use of the lantern slides referred to in this conference.

### DISTRIBUTION OF TUBERCULOSIS DEATH RATE

Some of the major battles in the national tuberculosis control program recently authorized by Congress will be waged in the ninety-two cities of 100,000 or more population, where about one out of every three tuberculosis deaths occurs, and where average tuberculosis death rates are about one third higher than in smaller towns and rural areas, Dr. Herman C. Hilleboe, chief of Tuberculosis Control Division, the U. S. Public Health Service, Federal Security Agency, said on August 3.

The Public Health Service has published tabulations, based on data from the U. S. Bureau of Census for the three year period 1939-41, centering around the census year 1940, Dr. Hilleboe said, which show extreme variations in the death rates for tuberculosis in large cities from as low as 15.6 per 100,000 among white persons in Grand Rapids, Mich., to as high as 275.5 per 100,000 among non whites in Newark, N. J.

"Studies are being made to discover what favorable conditions are responsible for the low tuberculosis death rates in some of our large cities," said Dr. Hilleboe, "and several of the cities with high mortality rates already have undertaken vigorous tuberculosis control programs to find and remedy the causes for their large tuberculosis death rates."

The average yearly tuberculosis death rate in the ninety-two large cities was 55.4 per 100,000 population, compared with rates of 43.5 in places of 2,500 to 100,000 population, and 41.1 in rural areas.

These tabulations show only the "crude" rates for both sexes and all ages, Dr. Hilleboe pointed out.

Other studies, as yet unpublished, show that although tuberculosis death rates for males are higher in cities than in rural areas, the rates among fe-

males in rural areas are higher than in cities, except for very young girls. These facts mean that special problems, which must be solved in the national tuberculosis control program, exist in smaller cities and rural areas, as well as in large cities, said Dr. Hilleboe.

Fourteen of the ninety-two cities had tuberculosis death rates of less than 30 per 100,000 among all races. These cities, and their rates for all races were:

Grand Rapids, Michigan, 15.6; Salt Lake City, Utah, 19.3; Minneapolis, Minnesota, 20.9; Des Moines, Iowa, 22.7; Spokane, Washington, 23.8; Akron, Ohio, 25.1; Duluth, Minnesota, 25.1; Flint, Michigan, 25.5; Wichita, Kansas, 26.4; Long Beach, California, 26.6; St. Paul, Minnesota, 26.8; Peoria, Illinois, 27.0; Springfield, Massachusetts, 27.2; Somerville, Massachusetts, 27.7.

Twelve cities had tuberculosis death rates of more than 74 per 100,000 among all races:

Nashville, Tennessee, 79.3; Norfolk, Virginia, 80.6; New Orleans, Louisiana, 81.0; Baltimore, Maryland, 82.1; Washington, D. C., 82.7; Birmingham, Alabama, 83.7; Atlanta, Georgia, 86.5; Memphis, Tennessee, 89.1; Jacksonville, Florida, 89.4; Sacramento, California, 97.5; Chattanooga, Tennessee, 113.7; San Antonio, Texas, 151.7.

Rates for all races were highest in the South Central cities and lowest in the Mountain cities. Rates for whites were lowest in the North Central and the New England and Atlantic states, and were highest in the South Central and Pacific. Conditions were almost exactly opposite for nonwhites, for whom rates were lowest in the South Central and the Pacific states and highest in the North Central and the New England and Atlantic

### AMERICAN COLLEGE OF SURGEONS CANCELS 1944 CLINICAL CONGRESS

The American College of Surgeons, upon action of its Board of Regents, has canceled its Annual Clinical Congress because of the acute war situation that has developed, involving greater demands than at any time in the past upon our transportation systems for the carrying of wounded military per-

sonnel, troops, and war material. The Congress was to have been held in Chicago, October 24 to 27.

Dr. Irvin Abell, of Louisville, Chairman of the Board of Regents, in making the announcement, said that this action was taken after consultation with officials in Washington.

# History of Medicine

## HISTORY OF PUBLIC HEALTH IN CHAUTAUQUA, CATTARAUGUS, AND ALLEGANY COUNTIES

H. R. O'BRIEN, M.D., M.P.H., Charlottesville, Virginia

PASSING over the missionary priest, the fur trader, and the Colonial soldier, our story begins with the settling of these three counties after the Revolution. The first white settlement in this area came in 1796, when Steven Cole arrived in Elm Valley, near Andover. His son, Daniel (February 18, 1797), was the first white child born in Allegany County. John McHenry was born near Westfield, early in 1802. On April 30, 1806, Hiram Warner McClure was born at Franklinville. Other settlers followed, and the three counties were organized within that decade. Table 1 shows the growth of population since.

Our knowledge of health conditions in those pioneer days is limited. In 1807, we hear, some terrible sickness became epidemic in and around Olean, attacking Indians and whites. A squaw was tortured to death as a witch by other Indians, who thrust burning sticks down her throat. An early physician of Allegany County wrote in later years:

"The summer of 1804 was moderately warm, while the winter was intensely cold. Much snow fell, and lay longer than ever before known. The new settlements were healthy; the winter diseases were inflammatory. These diseases continued during 1805 and 1806, and the abusive use of mercury sacrificed numbers. The character of the inflammatory fever varied with localities in 1807. Near streams whose course was obstructed by dams, strong symptoms marked its attack, whereas on high ground the approach was insidious and more difficult of control. Ophthalmia prevailed in July and August; influenza was epidemic in September. The season of 1808 resembled the one previous. A typhoid appeared in January and continued until May. The treatment was careful depletion followed by judiciously given stimulants. In 1811 bilious fever prevailed. In the spring of 1812 a few sporadic cases of pneumonia typhoides, a previously unknown disease, first came to notice. It was the most formidable epidemic ever prevalent in this country. The disease became general in 1813 and caused great mortality. By spring, 1814, it entirely disappeared. The principal disease up to 1822 was dysentery; it was most fatal to children. The change since 1828 is such that death from fevers became a rare occurrence and consumption took precedence."

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

Senior Surgeon (R), USPHS; formerly Commissioner of Health of Cattaraugus County.

Try to picture the pioneer scene. The hills were covered with virgin forests, in which the settler slowly chopped out a clearing and built his log cabin. Later he built a dam and gristmill on a nearby creek, to grind his grain and his neighbors'. In Cattaraugus and Chautauqua counties lumbering was the first major industry, great rafts of planks going down the Allegheny to build up Pittsburgh and the newer communities along the Ohio. A quart of whiskey cost twelve and one-half cents. These were strenuous days when deaths from "violent and accidental causes," and from malaria and dysentery were prominent. The pioneer mother bore large families of children and frequently reared many.

In 1816 Dan Huntley drove thirty cows from Cortland County to Franklinville and the first dairy appeared in Cattaraugus County.

Doctors came early to serve the new settlements. There were enough in Chautauqua County to form a county medical society in June, 1818, in "court week." This was only ten years after the organization of the Medical Society of the State of New York. Cattaraugus County followed in 1833, but this organization lasted only until 1844. It was started again in 1867.

There was little public health organization in those days. A State law of 1801 set up quarantine provisions, to be enforced in inland towns by two justices of the peace, who might appoint others to help. Following the appearance of cholera in New York City in 1832, a "cholera act" provided for local boards of health, with

TABLE 1.—COUNTY POPULATION ENUMERATED AT EACH DECENNIAL CENSUS

Year	Allegany County— Created April, 1806	Chautauqua County— Created March, 1808	Cattaraugus County— Created March, 1808
1810	1,942	Not shown	Not shown
1820	9,330	12,568	4090
1830	26,276	34,671	16,724

1860	41,881	58,422	43,886
1870	40,814	59,327	43,909
1880	41,810	65,342	55,806
1890	43,240	75,202	60,866
1900	41,501	88,314	65,643
1910	41,412	105,126	65,919
1920	36,842	115,348	71,323
1930	38,025	120,457	72,398
1940	39,681	123,580	72,652

control over quarantine and nuisances. Each local board made its own regulations. This act soon lapsed, and it took the new epidemic of 1849, when five thousand people died in New York City of cholera, to revive the law permanently. The law of 1850 required the appointment of boards of health and health officers in every city and village, and of health officers in each town. Powers of the boards to abate nuisances were strengthened in 1867 after another epidemic of cholera appeared.

In 1860 local school boards and trustees were directed by law to exclude from the common schools any child who had not been vaccinated. They could furnish vaccine to those whose parents were unable to do so. The law was frequently ignored.

In 1850 the president of the State Medical Society urgently recommended the establishment of a State Board of Health. A standing committee on hygiene and medical statistics became a part of the Society's organization. The laws of 1847 had made provision for registration of births, deaths, and marriages, but in 1870 the Society was again urging legislation to make registration effective. The same year physicians returning from Europe were bringing back clinical thermometers. The telephone was invented.

Dr Thomas J. King of Machias served in the Assembly in 1876 and 1877. He was appointed chairman of the committee on public health, and probably had something to do with the crystallization of sentiment for a State Board of Health. The law was passed, and the board began to function in 1880. Its annual reports reflect the conditions which had obtained for decades past, and which had called the board itself into being.

In the world of the 80's, this area was predominantly rural. The cities were much smaller than now, but the towns themselves, outside of the corporation limits, had more people living in them than they have today. Roads were dirt or corduroy. The railroads had come, and the great body of travel was over them. Municipal water supplies were being installed in a few places—in Salamanca (1881) in Jamestown, Fredonia, Olean, Wellsville and Little Valley a year or two later. Dunkirk boasted a city water supply in 1870 or thereabouts. There were scattered stretches of local sewers in some municipalities but aside from Chautauqua Assembly Grounds no place had a sewage disposal plant before 1912.

The germ theory of disease was beginning to be discussed in scientific circles but did not figure in public thought. In medical opinion typhoid and diarrhea were connected with sewage, but

diphtheria was a puzzle. In June, 1880, some 60 cases occurred in the town of Harmony, Chautauqua County, with 22 deaths. The epidemic, which attacked school children especially, was ascribed to impure drinking water.

It was part of the task of the newly formed State Board of Health to perfect some form of health organization in every corner of the State. Towns and villages that had not appointed a board of health or a health officer (a physician) were induced to do so. Registration of births and deaths and reporting of communicable diseases were taken up in earnest. School boards (for the schools were the concern of State health authorities until the transfer in 1914) were admonished on vaccination and on the shocking condition of many school buildings.

Toward the end of the decade the Board had local figures to report that were fairly reliable and complete, although they did not give county totals. The statistics for 1888 are particularly interesting. Olean, with some 7,000 people reported 138 deaths. One was from typhoid, 11 were from diarrhea, 3 from scarlet fever, 9 from "diphtheria and croup," and 11 from "consumption." Almost one third of all deaths were due to communicable disease. The same group of diseases was responsible for only 2.5 per cent of all the deaths in our three counties in 1938, fifty years later. In those days about one third of the deaths occurred in those under five years of age. In 1938 it was one fourteenth.

An Indian woman who had been on exhibition at the International Fair in Buffalo fell sick in September, 1888, and died of smallpox on the Cattaraugus Reservation. Three other women contracted the disease and were cared for in a freshly constructed log hospital. They died and were buried without coffins. A man recovered and the hospital was burned. Meanwhile a local physician had vaccinated five hundred persons and stopped the epidemic. Three Indians ran away to the Allegany Reservation where five cases appeared. These were cared for in a shanty, with a shed for two Indian nurses. Four of the patients died.

The '90's show evidence of distinct progress in several directions. Yet in 1892 a State physician wrote of Dunkirk:

"I found a vigorous and excellent board of health. A house to house inspection has been made, and all conditions that imperil health have been suppressed. The great source of danger to this city, if cholera should appear, is that the sewage of the city is emptied into the lake less than a quarter of a mile from the intake of the water supply."

The following year a State visitor reported that Olean had a health officer, a board of health and an inspector.

"The town is well-sewered, but where sewer connections do not exist, night soil is deodorized and taken out on farms.

"The water supply is from wells near the river supplemented by water from the river. A new well is being dug but the water seems to be practically river water. . . .

"An isolated place on Fourth Street on the river has been selected for a hospital."

At that time each city or village was supposed to have some structure operating or available as a pesthouse. It was not until the Jamestown City Hospital was built in 1911 that a proper isolation pavilion was available in this area.

There was an epidemic of grippe in the State at some period of each year from 1889 to 1894, carrying off from three to eight thousand people. The testing of cattle for tuberculosis began in 1893. The program was entirely voluntary and there was no compensation for slaughtered cattle. A herd at Dunkirk was included in 1894.

For the period from 1893 through 1899, Jamestown averaged 29 deaths from "consumption" a year, a mortality of 155 per 100,000.

Communicable diseases made 1893 a terrible year for Jamestown, then with 18,627 inhabitants. Seven people died of cerebrospinal meningitis, 10 of typhoid, and 15 of diarrhea, 10 of scarlet fever, 34 of consumption, and even 2 of the malaria of pioneer days, and 109 of "diphtheria and croup." Antitoxin was only beginning to come into practical use. The following year 17 died of diphtheria in Dunkirk, with a population of 10,000 people, and 27 of meningitis.

The century turned, and diphtheria was becoming less deadly. Eleven thousand people died in the State in six months of grippe. A sewage treatment plant was recommended for Fredonia. In 1901 the State Board of Health became the State Department of Health. Jamestown had 16 deaths from typhoid in 1904, 5 from diarrhea, and even one from malaria. Two years later Wellsville had 29 cases of typhoid, traced to contamination in its well and reservoir system.

In the latter part of the first decade the historian finds he is meeting something new; he is watching the development of modern public health work. In 1907 the State Department of Health appointed a Tuberculosis Advisory Committee, including Homer Folks and Livingston Farrand. A new law required the reporting of all cases of tuberculosis.

This development of present-day public health has several features. A carefully planned campaign against tuberculosis shows what can be done to overcome one disease through early diagnosis, adequate treatment, isolation of carriers, and examination of contacts. New agents

appear in public health: the lay organization, the public health nurse, the whole-time administrator, the syphilis clinic, the public health laboratory, the county department of health, State aid, the sanitary engineer, the public health educator, the mental hygienist, and the nutritionist. These may be traced in our three counties.

The organization of local branches reflected the widespread interest in the new campaign against tuberculosis conducted by the State Department of Health and the State Charities Aid Association. In 1909 the Olean Tuberculosis Committee was formed, followed two years later by a county committee; the two merged in 1920 into a Cattaraugus County Tuberculosis and Public Health Association. Tuberculosis committees were organized at Jamestown and Dunkirk in 1909. Two years later a County Federation united these two and a number of village committees. The Allegany County Committee on Tuberculosis was organized in 1917. These groups paid for public health nurses to visit tuberculosis patients. Their value demonstrated, these nurses were later taken over by counties or cities. The groups helped get sanatoriums built and clinics held. Some still maintain fresh-air camps. They have given interest and support to general health programs.

Another lay group organized the Visiting Nurse Association of Jamestown in 1909. This organization has grown through the years, employing now six public health nurses, in addition to a supervisor, to do bedside nursing. It holds various clinics and conducts a fresh-air camp. Olean followed Jamestown closely and organized a Visiting Nurse Association early in 1910.

The Olean Red Cross Society was organized in March, 1917, and for two years was very busy with war work and with the conditions arising from the great influenza epidemic of 1918. After demobilization, however, it became interested in child welfare work in cooperation with the Olean Antituberculosis Society, which maintained two nurses and a free dispensary. The Red Cross took over bedside nursing in Olean but dropped it in 1943. From 1916 to 1920 the Dunkirk Red Cross sponsored the nurse in that city.

Today the public health nurse is indispensable. The first one appeared in this area on March 1, 1909, under the Jamestown Visiting Nurse Association. The same year the Dunkirk and the Olean Tuberculosis Committees each appointed a nurse to do antituberculosis work. The Allegany and Cattaraugus County associations followed. Sooner or later this work was taken over by public appropriation. Jamestown and Olean had city nurses in the same decade. The first school nurse was appointed in 1921, in

Dunkirk, Jamestown and Olean soon followed. The accompanying table groups the public health nurses today. The service in Cattaraugus County is largely generalized, in the two others nursing is largely concentrated on the school-age groups (See Table 2).

During the depression some thirty registered nurses in need in this area were employed by Works Progress Administration and assigned to the larger organizations to assist. Although untrained in public health nursing, they were very helpful. They served in the period 1934-1938.

From January 21, 1914, public health in New York took fresh strides forward, under Hermann M. Biggs. The year before he had aided with legislation which replaced the Advisory Committee with a Public Health Council having power to enact a State sanitary code. The new law also provided for twenty sanitary districts in the upstate area, each to be served full time by a physician selected under civil service. Commissioner Biggs appointed Dr. John J. Mahoney, city health officer of Jamestown, district sanitary supervisor for the Jamestown district, comprising these three counties. Local health officers were now visited frequently and were stimulated to take short courses of training in their duties. The State sanitary code began to be enforced. Today Chautauqua and Cattaraugus counties comprise the Jamestown subdistrict under Buffalo, while Allegany County is supervised from Hornell.

In 1915 the Legislature made vaccination of school children against smallpox no longer compulsory, save in cities over fifty thousand in population or in the presence of smallpox. The supervision of health work in schools was transferred to the State Department of Education.

In 1916 the efforts of the tuberculosis societies in Cattaraugus County resulted in the building by the Board of Supervisors of Rocky Crest Sanatorium on the hill south of Olean. In the same year the city of Olean organized a venereal disease clinic under the direction of Dr. L. J. Atkins. The Olean Chamber of Commerce made the establishment of full time county health service part of its program.

The same popular interest in tuberculosis which had built Rocky Crest soon led to the

erection of a larger institution in Chautauqua County. Using a bequest by Mrs. Elizabeth Newton, the supervisors opened the Newton Memorial Hospital at Cassadaga in 1920. Here Dr. Walter Rathbun's work in examining high-school students is nationally known.

The Allegany County supervisors purchased a site for a sanatorium in 1917, but no building was erected. Patients from this county were usually sent to Rocky Crest until the district State sanatorium at Mt. Morris was completed in 1937.

The State Department of Health began work in 1919 for children crippled by infantile paralysis. The first clinic in this area was held in Jamestown on September 24.

Dr. Biggs, who had long been concerned about health conditions in rural areas, succeeded in 1921 in securing legislation permitting a board of supervisors to set up a county health district covering the entire county or omitting such cities as did not vote to be included. The Milbank Memorial Fund announced that it wished to demonstrate the value of such health work in an upstate county and selected Cattaraugus County from the group of applicants. On January 10, 1923, the Board of Supervisors voted to organize a county health district, and appointed the first county board of health in New York State. Later in the month the cities of Olean and Salamanca voted to be included.

The formation and development of the County Department of Health was in large measure due to the support of Miss Lilla C. Wheeler, of Portville, a woman of vision, sympathy, and energy, who had long been interested in public health work both in the county and in the State.

The Cattaraugus County Department of Health, in serving the people of its county, has made distinct contributions to public health generally. Before the war one public health nurse was available for each 4,000 to 4,500 inhabitants. The nurse lives in her district of three or four townships, and gives a thoroughly generalized service, including school nursing and bedside nursing. From the beginning she has assisted the physician in home deliveries. This was the first rural agency in the United States to offer this service. The Olean City Laboratory, which had been organized by Dr. J. P. Garen in 1919, was taken over to serve the entire county. It combined clinical service to the practicing physician with a wide range of public health work. In close cooperation with the sanatorium, local tuberculosis clinics were set up in the district health stations, aiding early diagnosis. Dr. S. A. Douglass and later Dr. John H. Korn organized a system of careful follow-up of contacts of active cases, and of bedside consultation serv-

ice. A sanitary inspector and later a sanitary engineer, supervising the sewage disposal and the milk and water supplies of the county, became part of the staff. Birth and death certificates from the local registrars go through the county office. The Olean syphilis clinic was taken over and another was organized at Salamanca. A special health education project under Ruth E. Grout produced a handbook in this field. Dr. L. D. Bristol, Dr. S. A. Douglass, and Dr. R. M. Atwater developed a well-rounded department.

A school hygiene service was also organized in 1923, to coordinate the school health work of the county. Dr. C. A. Greenleaf, Olean school physician long associated with antituberculosis work, became director.

The board of supervisors steadily increased their support of the County Department of Health, which is long since indigenous. The Milbank Memorial Fund, which at one time devoted over \$80,000 a year to the demonstration, made its last contribution in 1940. The State Department of Health matches the county expenditures dollar for dollar. Since 1932 this matching has included the operation of the sanatorium, which then became an integral part of the department.

State aid on this scale of 50 per cent was a feature of Dr. Biggs' plan to help rural counties.

In 1923 it was extended to cover almost any phase of health activity conducted by a county. Under this law Chautauqua and Allegany counties receive aid for their county nursing services, and under a similar law for their approved laboratories.

Allegany County opened a county laboratory in Belmont in 1915. Since 1929, Dr. E. K. Kline has served as director of this laboratory as well as that of Cattaraugus County. The Jamestown Municipal Laboratory was started in 1926, and the Chautauqua County Laboratory at Dunkirk in 1938. All four are approved and receive State aid.

School districts are required by law to have medical inspectors, and may also employ school nurses. They receive State aid which may reach 85 per cent of the amount spent.

The construction of sewage treatment plants lagged far behind that of community water systems. The first disposal plants were built in 1912 at Westfield and Franklinville. Federal help in the late '30's aided many communities in building or modernizing sewer systems.

Olean, Jamestown, and Dunkirk have long had sanitary inspectors, whose work was extended to milk supplies.

Tuberculin testing of cattle, started in the early

'90's, was not put on a county-wide, compulsory basis until much later. All three counties are now under the accredited herd plan—Cattaraugus and Allegany since 1921, Chautauqua since 1923. As a result, tuberculosis of the bones and joints in children has practically disappeared.

The campaign against infectious abortion in cattle, caused by the organism which incites undulant fever in man, is repeating the steps in development of the tuberculosis campaign. Blood-testing is largely optional, and funds to assist the owner of a reacting animal are limited. Yet more and more herds are being tested.

Arranging for the care of the mentally ill is, in New York State, among the duties of the local health officer. The Willard State Hospital, opened in 1869, receives patients from Allegany County, and the Gowanda State Hospital (1898) serves Chautauqua and Cattaraugus counties. Clinics in various cities began to be organized in 1916. They serve adults with early mental disease and aid parents with child-guidance problems.

In communicable diseases several events are noted in these decades. The epidemic of influenza in the fall of 1918 swept this area, as it did the rest of the world. In September, 1929, typhoid suddenly appeared in Olean, producing, in all, 245 cases and 15 deaths. Investigation showed the epidemic was due to lax handling of the city water supply. A bond issue of \$400,000 was raised by the city to meet claims. Diphtheria, which had been growing less and less severe, was hurried out of the picture by intensive immunization of preschool children beginning in 1925.

In 1938 the three counties together had just four cases with no deaths.

The value of a strong local health organization was shown in July, 1942, when the worst flood in its history swept over Olean. Aid came from outside but it was primarily the County Department of Health, under Dr. W. R. Ames, which met the situation, and so organized the work in control of water and milk supplies and in immunization that no epidemic of any kind appeared, and not a single case of typhoid.

Looking back over this century and a half we can see how far New York, as reflected in these three counties, has come. Problems in public health still remain to be solved. The degenerative diseases of the aged are one; over half of the people who die in this area are 65 years old or over. Cancer is another. In the list belong: maternal welfare, nutrition, mental hygiene, accidents, housing, and on the horizon, arthritis. Public health organization is a problem in itself.

In the century and a half just ahead we may ex-

pect progress in all these fields and others. Each generation needs its own challenges to meet

Perhaps 2094 will think that we of 1944 were a bit on the primitive side

ARMY AND NAVY NO LONGER NEED LARGE QUININ PRODUCTION

The large scale production of quinine or totaquine, a form of quinine, is not now considered a matter of importance for the management of malaria among the Army and Navy personnel, the National Research Council's Board for the Coordination of Malarial Studies declares in an official report on the use of quinaquine (atabrine), a synthetic quinine substitute, in the prevention and treatment of malaria. The report is published in the *Journal of the American Medical Association* for August 5. Commenting on the report, the

administered, is fully as effective as quinine in the termination of the acute attack and is safer than quinine. The intramuscular injection of quinaquine is highly effective in securing a rapid therapeutic response. Evidence is not at hand to decide on the relative merits of quinaquine administered intramuscularly as compared with quinine administered intravenously in patients with fulminating cerebral malaria.

"3 In the Therapy of Vivax Malaria—Neither quinaquine nor quinine can be relied on to prevent relapses in vivax malaria following the discontinuation of therapy, attacks is significant, than following quinaquine, currently used by the armed forces.

"4 In the Therapy of Falciparum Malaria—There is convincing evidence that quinaquine not only suppresses the clinical symptoms of falciparum malaria but also cures this malignant form. The evidence of a similar curative effect of quinine is not conclusive.

"5 Totaquine (USP)—Because of its content of crystallizable cinchona alkaloids, totaquine (USP) has activity which approximates that of quinine and therefore can be used as a substitute for quinine when given orally. The antimalarial activity of totaquine (USP) is dependent on the amount of crystallizable alkaloids in the preparation rather than on the specific amount of each individual alkaloid. Gastrointestinal disturbances occur more frequently following the use of the present totaquine (USP) than they do following the use of quinine or quinaquine.

"On the basis of the foregoing statement, it is resolved:

"1 That no advantage, and possible disadvantage, would accrue to the armed forces were quinine or totaquine to replace quinaquine for the routine suppression and treatment of malaria.

"2 That the large scale production of quinine or totaquine is not now considered a matter of importance for the management of malaria among Army and Navy personnel. It is possible that a supply of totaquine in excess of the present stockpiles may be required for therapy in civilian populations temporarily under the jurisdiction of the armed forces in occupied territory where immediate dissemination of information concerning the use of quinaquine (atabrine) is not practicable. In this connection it should be kept in mind that after the war the over all need for all established antimalarial drugs will continue to be great."

BOARD FOR THE COORDINATION OF MALARIAL COUNCIL REPORT

R. F. Dittus, Lieut. Col. (MC), AUS, A. R. Dochez, OSRD, E. G. Håkansson, Capt. (MC), USN, E. K. Marshall, Jr., O. R. McCoy, Maj. (MC), AUS, F. T. Norris, Lieut. Comdr. (MC), USN, W. H. Schell, USPHS, J. A. Shannon, and G. A. Caden, Jr., Secretary.

prevention, should be able to eliminate malaria from every civilized nation. That would be, indeed, a blessing derived from the most destructive and costly war the world has ever known.

The most common form of the disease in temperate countries is vivax malaria, named after the species of the malaria parasite which causes the benign tertian form in which the attacks of chills, fever, and sweating occur every other day. It rarely causes death. The most severe form is falciparum malaria, which is more prevalent in the tropics and is responsible for practically all deaths due to malaria although it lends itself to treatment if recognized early. It is named after another species of the malaria parasite.

The official report published in the *Journal* says: "On May 31, 1941, the Board for the Coordination of Malarial Studies adopted the following resolution concerning the relative value to the armed forces of quinaquine hydrochloride, USP (atabrine) and quinine."

At hand justifies the following statement:

"1 In the Suppressive Therapy—Quinaquine (atabrine) has proved to have all the antimalarial properties ascribed to quinine in the suppression of malaria during and subsequent to exposure to infected mosquitoes. Effective suppression can be accomplished over long periods of time by proper use of quinaquine. Available evidence indicates that this end may be achieved without danger to the individual.

Earlier reports indicated a significant incidence of gastrointestinal disturbances in certain groups of men receiving suppressive quinaquine therapy. For practical purposes, these adverse reactions can be avoided by proper administration of the drug. Quinine, in doses adequate to assure suppression of malaria equivalent to that produced by quinaquine in the dosage currently used by the armed forces, is frequently attended by symptoms of cinchonism.

Quinaquine has been demonstrated to prevent consistently the development of falciparum malaria when the drug is administered in proper dosage before, during, and after exposure.

"2 In the Therapy of the Acute Attack—Experience in the past two years has demonstrated conclusively that quinaquine (atabrine), when properly

## Special Article

### DIPHTHERIA IN AN "ADEQUATELY" IMMUNIZED COMMUNITY

BERWYN F. MATTISON, M.D., M.P.H., Kingston, New York

THE protection level against diphtheria for any community may be taken as the summation of its natural and its artificial immunization levels. These are not the only factors governing the incidence of the disease, for certainly the prevailing contact rate (a measure of crowding, population flux, and social interchange) is also important as well as the virulence of the prevailing strain of *Corynebacterium diphtheriae*. Possibly there is also some degree of nonspecific immunity varying with nutritional and general health standards. But the two kinds of specific diphtheria immunization are our principal safeguards.

The relationship of these two factors is not constant. During the past twenty years we have seen a marked decrease in incidence of the disease. This has been concomitant with and undoubtedly conditioned by the increasing use of various artificial immunizing agents. It was pointed out by Godfrey in 1932<sup>1</sup> that the age of the children so treated was of prime importance in achieving a general community protection against epidemics. Thus it was the experience in several localities that outbreaks continued in spite of the artificial protection of over 50 per cent of the school-age youngsters, but when to that was added 30 per cent or more immunizations among preschool children, a striking decline occurred in the community as a whole.

Recently (1940) an analysis<sup>2</sup> of the changing relationship of natural and artificial diphtheria immunity has indicated that in 1922 immunization of 30 per cent of the children under 5 years of age would have resulted (with the then existing rates of natural immunization) in about 52 per cent of that population being protected. But in 1938, with the much lower rate of natural immunization, 55 per cent of the group under 5 would have to be artificially immunized to achieve the same level of community protection.

This is the natural consequence of vastly decreased diphtheria prevalence during that interval, with its associated lowering of carrier frequency and hence of subclinical exposure or infection which might stimulate natural immunity. As community experience with the disease decreases, it would seem that our administration of diphtheria toxoid must increase to compensate for it.

The present report deals with a small outbreak of diphtheria which occurred between October, 1943, and March, 1944, in an upstate New York city whose previous history with regard to natural and artificial immunity is unusually complete. Kingston, New York (1940 census population 28,589), had been the site of an extensive Schick survey in 1922 and again in 1938,<sup>2,3</sup> together with a carrier survey at the later date. The data obtained in these studies formed the basis of the estimate mentioned above as to the degree of increase in toxoid administration necessary to counteract a lessening natural resistance to the disease. Only 2 cases of diphtheria had been reported in the city in the ten years preceding the outbreak.

Table 1 shows the incidence of reported cases during the outbreak. From the first appearance of cases intensified efforts were made by the City Health Bureau to secure immunization of the preschool group. During January and February this was supplemented by a school clinic program during which nearly every child of school age was given either a complete course of alum-precipitated toxoid (two 1 cc. doses at three-week intervals) or a restimulation dose if they had been previously protected three or more years before.

TABLE 1.—OCCURRENCE OF DIPHTHERIA CASES BY MONTH OF ONSET

October	November	December	January	February	March
3	4	11	5	1	4
Total number of reported cases—28					

As is seen in Table 2, the cases occurred predominantly among school-age children. There was no definite aggregation of cases in any one school district, or in any one part of the city. Information regarding milk supplies was secured on all cases and again there was no undue association of cases with any one supply. Seven patients had a history of household contact prior to their onset; and 21 were apparently "primary" cases.

With the first reported cases, laboratory examinations of throat cultures increased sharply. It became apparent from these numerous examinations, mostly on contacts and symptomatic patients, that a considerable number of

Age of Patient	Number of Reported Cases
All ages	28
Under 5 years	1
5-9 years	11
10-14 years	10
15-19 years	2
20 years and over	4

passive carriers were present in the city. Table 3 shows the number of examinations done each month, and the number of carriers (of virulent *C. diphtheriae*) and cases discovered. This is in marked contrast to the 1938 survey results (1 virulent culture out of 3,223 examined).

In all of the cases cultured the diphtheria organism was predominant and frequent checks were made on blood agar plates to rule out streptococci and other causative agents. In the carriers, *C. diphtheriae* were occasionally present together with various other organisms.

TABLE 3.—THROAT CULTURES EXAMINED AND CASES AND PASSIVE CARRIERS DISCOVERED ACCORDING TO MONTH OF OUTBREAK

Month	Total Number of Cultures	Total Persons Cultured	Number of Positive Persons	Cases	Carriers
Total	1,525	718	63	28	35
September	8	8			
October	50	34	3	3	
November	365	202	16	4	12
December	425	160	14	11	3
January	356	145	23	5	18
February	191	96	2	1	1
March	130	73	5	4	1

The nature of the disease, in general, was mild, especially where toxoid had been given at some earlier date. In only about half a dozen of the cases were there marked constitutional symptoms, but in all of those reported definite local lesions occurred. Most frequently these were on the tonsils or fauces; no laryngeal cases were observed. The administration of antitoxin was prompt in most instances. There were no deaths, and, to date, there have been no late cardiac or nervous complications.

As usual, considerable difficulty was encountered in clearing up both cases and carriers bacteriologically. A variety of local applications was tried and 7 of the cases only became negative for *C. diphtheriae* after tonsillectomy. The median interval between the first positive culture and the second negative release culture for 28 of the patients on whom information is complete was thirty-eight days; the same interval for 24 passive carriers was fourteen days.

Control measures consisted of isolating cases and quarantine of child's household contacts as required by the Sanitary Code; intensification of preschool immunization, which was in-

creased 500 per cent over the same period for the previous year; and immunization of 2,684 grade-school children (1,868 were restimulations)—representing about 80 per cent of that age group.

At the time of the school immunization clinics a survey was done to determine the past immunization status of each child. The results give an unusually complete picture of the artificial protection pattern in the age groups included. Table 4 is based on an analysis of the findings in five schools picked at random and including 1,160 children between 4 and 15 years of age. Most of the recorded immunizations had been done with toxoids produced by the Division of Laboratories and Research of the New York State Department of Health.

TABLE 4.—SCHOOL CHILDREN SURVEYED IN JANUARY, 1944, REGARDING HISTORY OF PREVIOUS DIPHTHERIA IMMUNIZATION

Age	Total	Previously Immunized	Not Previously Immunized	Percentage with History of Earlier Immunization
All ages	1,160	866	294	74.7
4 years	26	17	9	65.5
5 years	81	69	12	85.3
6 years	114	82	32	71.9
7 years	131	91	40	69.5
8 years	117	50	37	68.4
9 years	141	109	32	77.4
10 years	147	109	38	74.2
11 years	144	114	30	79.2
12 years	116	89	27	76.8
13 years	67	55	12	82.1
14 years	50	34	16	68.0
15 years	26	17	9	65.4

It is of interest to note that below the age of 13 years more than 30 per cent of each age group was known to have received immunization before the age of 5 years (Table 5).

TABLE 5.—PROPORTION OF CHILDREN WHO HAD RECEIVED DIPHTHERIA IMMUNIZATION BEFORE THE AGE OF 5 YEARS

Age at Survey	Total	Immunized	Immunized Before the Age of 5	Percentage
All ages	1,160	866	571	49.3
4 years	26	17	17	65.5
5 years	81	69	62	76.5
6 years	114	82	69	60.5
7 years	131	91	71	54.2
8 years	117	80	56	47.9
9 years	141	109	59	56.8
10 years	147	109	70	47.6
11 years	144	114	65	45.2
12 years	116	89	42	36.2
13 years	67	55	19	28.4
14 years	50	34	14	28.0
15 years	26	17	6	23.1

These figures supplement and confirm the reported immunizations of children under 5 years as recorded by the State Department of Health. The latter are expected to be somewhat lower, owing to incomplete reports from private physicians of their toxoid injections. Table 6 gives the

TABLE 6.—PROPORTION OF ESTIMATED POPULATION UNDER 5 YEARS REPORTED IMMUNIZED AGAINST DIPHTHERIA, KINGSTON, NEW YORK, 1935-1944

Year	Percentage of Children Under 5 Years Reported Immunized
Jan. 1, 1935	48
Jan. 1, 1936	51

Jan. 1, 1944	46

estimated proportion of the population of Kingston under 5 years reported as immunized for each of the past ten years.

In view of the drop of reported preschool immunizations at the beginning of 1943 to a figure well below the 55 per cent level laid down in 1940 as the new danger line, it might have been expected that an outbreak would occur, but presumably the preschool group would have suffered had that been the principal cause. As we have seen, the cases actually fell predominantly in the 5-14 year age span.

Two additional observations may be relevant. First, of the 866 children in this group who had been immunized, definite information as to the date of immunization was secured on 755: 544, or 72.0 per cent, were known to have been given their injections more than five years before the outbreak.

Distributing the 111 immunizations known to have been done, but with no date of administration according to the same proportion—80 of these were probably performed more than five years earlier. Thus we may assume that 624 of the immunized group had been inoculated more than five years before.

According to some investigators,<sup>4,5</sup> as many as a third of those immunized with one dose of A.P. toxoid will have lost that protection five years after administration. At this rate at least 208 of the immunized group (if they received the then prevailing dosage: 1 A.P. or 2 fluid toxoid injections) would again be susceptible. This would mean a protection level no higher than 57.7 per cent instead of 74.7 per cent among the school-age children.

This loss of artificial immunity, in the absence of natural immunizing forces in the community, and in the absence of systematic re-stimulation doses of toxoid prior to the outbreak, may have been a major factor in the recurrence of the disease.

The second observation has to do with the nature of the immunizing procedures used in those persons who became ill. The artificial

immunization history of each case is summarized in Table 7.

Of the 18 patients who had been protected, definite information was available regarding the preparation and dosage in 15 instances.

Nine of these were given one dose of A.P. toxoid, and 4 were given two doses of fluid toxoid. Only 2 of the entire 28 patients had been given the currently recommended two doses of A.P. toxoid, and in both instances it was given five years before the outbreak.

## Summary

After being virtually free from diphtheria for ten years, Kingston, New York, suffered an epidemic of 28 cases between October, 1943, and March, 1944. Previous studies in this city had demonstrated a very low carrier rate (0.03 per cent) and a decreasing natural immunity. An analysis of the immunization histories of 1,160 school children indicated a history of past immunization in 75 per cent; reported immunizations among preschool children at the beginning of 1943 indicated that 44 per cent of them were protected.

The epidemic occurred predominantly in school-age children all of whom had either not been protected, had been given less than the currently recommended toxoid dosage, or had been immunized five or more years earlier with no subsequent restimulation. With the available data it is not possible to know whether the outbreak was due to some one or a combination of all of these factors.

## Conclusions

The decreasing prevalence of diphtheria has brought with it decreasing natural resistance to the disease. Levels of artificial immunization formerly adequate to protect a community may no longer suffice. Suggested steps to maintain

the necessary level of community protection include higher preschool protection rate, reimmunization of all children on entrance to school, administration of complete courses (two doses of A P toxoid or three doses of fluid toxoid) in every individual immunized

## IF POLIO STRIKES

Usually this will include recruiting of the needed medical services and the organization of your community's resources

or the purpose of so that medical While conditions will vary in different communities, any epidemic will create such a burden that all your resources may well be needed. Duplication can be avoided by careful planning with the state, county, city and local health, medical, and social agencies.

Because August and September are the peak epidemic months, we suggest you arrange now with your county and city health officers to inform you immediately of any increase of infantile paralysis in your area.

Advise these officers that your Chapter stands ready to assist them in rendering the maximum of aid to the people. To plan a unified program, suggest that a meeting be called of the local health officers, with officers of your Chapter and the State Representative of the National Foundation, and other persons such as the president of the County Medical Society, chiefs of staff and superintendents of all hospitals, editors of newspapers, the directors of the Crippled Children's Service, Public Health Nursing supervisors and Visiting Nurse or District Nurse Associations. There, the Chapter may outline its resources and services as well as those of the headquarters of the National Foundation.

### What Your Chapter Can Do

- 1 Make sure that no victim of infantile paralysis goes untreated because of lack of funds, regardless of age, race, creed, or color
  - 2 Pay all or any part of hospitalization costs as needed
  - 3
  - 4
  - 5
- consultation services, and medical and surgical equipment

— consult all pirators (For locations of those

nearest you, consult your publication No 24 "Repurators—Locations & Owners") If unable to

patients including and taxi or private car service for medical checkup in the post-isolation period

10 Employ clerical workers + health + grooms

12 Hire kitchen and floor helpers  
13 Serve as a cleaning house for volunteer personnel

14 Recruit nurses' aides or other lay volunteers to cut and prepare picks under proper professional supervision

15 Establish a telephone registry at Chamber

ing the serious strain on hospital wires

16 Supply literature for physicians and nurses. Provide widespread distribution of the "Bulletin" (When Polio Strikes—Helpful Hints for Everyone)

17 Arrange with local press and radio stations to issue appeals for wool, waterproof materials, wringers, washing machines, tubs, electric fans, footboards, etc., if they are needed

18 Arrange meetings and conferences in cooperation with Health Department and Medical Society

### What the National Foundation Will Do

1 Advise such additional funds to the Chapter as may be needed

2 Supply additional professional personnel upon the request of local medical and health authorities

3 Ship recipients from strategic locations upon request

4 Supply woolen material for hot packs free of charge

5 Supply splints free of charge—National Foundation News, National Information for Infantile Paralysis, 120 Broadway New York, New York Telephone BEckman 3-0500

## CHRISTMAS SEAL DRIVE TO OPEN NOVEMBER 20

The 1944 Christmas Seal Sale of the National Tuberculosis Association will open on November 20 and continue until Christmas. The annual Christ-

mas Seal Sale is the sole support of the National Tuberculosis Association and its 2,500 affiliated associations throughout the country.

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## "Penicillin Therapy"

POSTGRADUATE instruction in penicillin therapy will be given to the Nassau County Medical Society on October 31 at 9:00 p.m. at the Mercy Hospital auditorium in Rockville Centre. The speaker will be Dr. Frank L. Meleney, associate

professor of clinical surgery at the College of Physicians and Surgeons, Columbia University.

This instruction is presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

## Cortland County Society Holds Postgraduate Meeting

MISCELLANEOUS postgraduate instruction has been arranged for the Cortland County Medical Society, to be given Friday evenings at 8:30 p.m. at the Cortland County Hospital in Cortland.

On October 20 Dr. Albert G. Swift, professor emeritus of surgery and chairman and active head of the department of surgery at Syracuse University College of Medicine, will speak on "Surgical Lesions

on the Biliary Tract." The lecture on November 17 will be "Infections of the Genitourinary Tract," by Dr. Leo E. Gibson, professor of clinical surgery (urology) at Syracuse University College of Medicine. The lecture given by Dr. Gibson is presented as a cooperative endeavor by the Medical Society of the State of New York and the New York State Department of Health.

## Cancer Teaching Day in Ithaca

A CANCER teaching day will be held at Hermann M. Biggs Memorial Hospital, Ithaca, on October 17, under the auspices of the Medical Society of the County of Tompkins, the Medical Society of the State of New York, and the Division of Cancer Control of the New York State Department of Health.

Afternoon Meeting: 4:00 p.m.

1. Carcinoma of the Colon.

John Garlock, M.D., attending surgeon, Mt. Sinai Hospital, New York City.

2. Bone Tumors.

John J. Morton, M.D., chief surgeon, Strong Memorial Hospital, Rochester.

Evening Meeting: 7:30 p.m.

1. Epithelioma of the Skin.

Andrew H. Dowdy, M.D., associate professor of radiology, the University of Rochester School of Medicine and Dentistry.

2. Carcinoma of the Breast.

Frank E. Adair, M.D., executive officer, Memorial Hospital, New York City.

Dinner will be served at 6:30 p.m. at Hermann M. Biggs Memorial Hospital. The local committee consists of Joseph N. Frost, M.D., ex officio; Robert H. Broad, M.D.; Raymond D. Fear, M.D.; N. Stanley Lincoln, M.D.; Ralph J. Low, M.D.; Francis J. McCormick, M.D.; Henry B. Sutton, M.D.; and Willets Wilson, M.D.

## Tropical Medicine

POSTGRADUATE instruction in tropical medicine was given at a meeting of the St. Lawrence County Medical Society held September 14, at the Hepburn Hospital Auditorium, Ogdensburg.

Dr. Stockton Kimball, associate in medicine and pharmacology, University of Buffalo School of Medicine discussed the diagnosis and treatment of malaria and the dysenteries.

Luncheon at 12:15 p.m. at the Crescent Hotel preceded the lecture.

Postgraduate instruction in tropical medicine was

also given at a meeting of the Jefferson County Medical Society which was held at 6:30 p.m., September 14, at the Black River Valley Club, Watertown.

Dr. Kimball was again the speaker; he discussed the diagnosis and treatment of malaria and the dysenteries.

The programs were presented as a cooperative endeavor between the Council Committee on Public Health and Education of the Medical Society of the State of New York and the New York State Department of Health.

## Instruction in Psychiatry

POSTGRADUATE instruction in psychiatry was given to the Otsego County Medical Society at a meeting held at 6:30 p.m. on September 13, at the Tuna Cliff Inn, Cooperstown.

Dr. Foster Kennedy, professor of clinical medi-

cine, Cornell University Medical College, spoke on the neuroses as related to the manic-depressive constitution.

This program was presented under the auspices of the Medical Society of the State of New York.

# Thirty-Eighth Annual Meetings

## of the District Branches of the Medical Society of the State of New York

### PROGRAMS\*

#### First District Branch

Tuesday, October 24, 1944

Bellevue Hospital

28th Street and First Avenue

New York City

#### FOREWORD

A guide map of Bellevue Hospital will be found in the center pages of the printed program

Business meeting and election of officers will be conducted at 1:30 P.M.

#### MEDICINE

##### *First (Columbia) Medical Division*

9:45-11:30 A.M.—Conference with Presentation and Discussion of Cases

Dr. I. Ogden Woodruff and Staff  
(Ground A—A & B Building)

11:30-1:00 P.M.—Clinicopathologic Conference  
Drs. I. Ogden Woodruff and David M. Spain and Staff

(Ground A—A & B Building)

2:00-4:00 P.M.—Ward Rounds with Presentation and Discussion of Selected Cases

Dr. I. Ogden Woodruff and Staff  
(Ward A-3 and A-4—A & B Building)

#### CHEST DISEASES

9:00-10:30 A.M.—Ward Rounds (Medical)

Dr. J. Burns Amberson  
Ward D-2—C & D Building)

11:00-12:30 P.M.—Ward Rounds (Surgical)  
Dr. Adrian V. Lambert and Dr. J. Burns Amberson

(Ward C-5—C & D Building)

##### *Second (Cornell) Medical Division*

8:15-11:00 A.M.—Ward Rounds

Dr. Asa Lincoln and Staff  
(Ground B—A & B Building)

2:15-4:00 P.M.—Casualty Conference

Dr. John Richards  
(Ground A—A & B Building)

#### NEUROLOGY

10:00-12:00 NOON—Conference—Arachnoiditis Following Spinal Anesthesia

Dr. Foster Kennedy and Staff  
(Ward FI—F & G Building)

3:00-5:00 P.M.—Ward Rounds  
Dr. Foster Kennedy and Staff  
(FI & GI—F & G Building)

#### *Third (New York University) Medical Division*

2:15-4:30 P.M.—Round-Table Conference with

1. "The Treatment of Acute Myocardial Infarction"—Dr. Arthur C. DeGraff

2. "The Treatment of Thyrotoxicosis"—Dr. Elaine P. Rath

3. "The Clinical Use of Demerol"—Dr. R. C. Batterman

4. "The Treatment of Acute Myocardial Infarction"—Dr. Arthur C. DeGraff

5. "The Treatment of Acute Myocardial Infarction"—Dr. Arthur C. DeGraff  
(Ground A Class Room—A & B Building)

#### PEDIATRICS

2:15-4:30 P.M.—Round-Table Conference with

1. "The Treatment of Acute Myocardial Infarction"—Dr. Arthur C. DeGraff

2. "The Treatment of Thyrotoxicosis"—Dr. Elaine P. Rath

3. "The Problems of Adolescence"—Dr. Harry Bakwin

4. "Poliomyelitis"—Dr. Alfred Fischer

5. "Childhood Tuberculosis"—Dr. Edith Lincoln  
(G-6 Conference Room—F & G Building)

#### SYPHILOLOGY and DERMATOLOGY

"The Treatment of Industrial Dermatoses"—Dr. Frank Combes  
(Stewart Amphitheatre—I & K Building)

#### *Fourth (New York University) Medical Division*

9:00 A.M.-12:00 NOON—Presentations

1. "Treatment of Hyperthyroidism with Thiouracil"—Dr. Harry A. Solomon

2. "Newer Developments in the Treatment of Meningococcal Meningitis"—Dr. Emanuel Appelbaum

\* Programs for the annual meetings of the other District Branches appeared in the September 1 and September 15 issues.—Editor

3. "Penicillin in the Treatment of Empyema"—  
Dr. Emanuel Appelbaum
4. "The Importance of Heredity in Medical Disorders"—Dr. Max Trubek
5. "Chrysotherapy in Rheumatoid Arthritis"—  
Dr. Otto Steinbrocker  
(Ground A—A & B Building)

#### SURGERY

##### *First (Columbia) Surgical Division*

8:30-11:00 A.M.—Operations

Dr. C. J. MacGuire  
Dr. Roderick V. Grace  
Dr. Gaston A. Carlucci  
Dr. Philip C. Potter

(K-5—I & K Building)

10:30-1:00 P.M.—Ward Rounds

Dr. Walter W. Fischer  
Dr. Vincent Hurley  
Dr. Wallace Sheridan  
Dr. Louis Davidson

Wards L-5, L-6, and M-6—L & M Building)

##### *Second (Cornell) Surgical Division*

8:30-11:00 P.M.—Operations by Dr. Guilford Dudley and Staff

(K-5—I & K Building)

11:00 A.M.—12:30 P.M.—Staff Conference

Dr. Guilford Dudley and Staff

(M-4 Library—L & M Building)

#### UROLOGY

10:00 A.M.—12:00 NOON—Operations by Dr. Howard Jeck and Staff

K-6—I & K Building)

##### *Third (New York University) Division*

9:00-11:00 A.M.—Abdominal and General Surgery  
Dr. W. Howard Barber, Dr. Hippolyte M. Wertheim, Dr. Thomas J. Galvin, Dr. Victor Carabba, and Dr. Samuel Standard

(K-5 Operating Room—I & K Building)

9:00-11:00 A.M.—Fractures

"Rounds with Demonstration of Various Methods of Treatment"—Dr. Irwin E. Siris and Dr. John A. Lawler

(K-2—I & K Building)

#### SURGICAL RESEARCH

10:30-11:00 A.M.—Lantern Slide Demonstration:  
"Studies of Surgical Convalescence"—Dr. Co-Tui and Dr. George R. Gerst

(I & K Amphitheatre—Ground Floor, I & K Building)

11:00 A.M.—12:30 P.M.—Surgical Staff Conference

Dr. Arthur M. Wright, Director

(I & K Amphitheatre—I & K Building)

#### ANESTHESIA

9:30 A.M.—12:00 NOON—Therapeutic Nerve Block, Incidence of Postoperative Anesthetic Complica-

tions, Reflex Circulatory Derangement During Surgery

Anesthetic Clinics

Nerve Block—Therapeutic

a. Lumbar

b. Sympathetic

c. Paravertebral

Suprascapular for Painful Shoulder

Other cases available

Dr. E. A. Rovenstine, Director of Anesthesia  
(K-6—I & K Building)

#### OPHTHALMOLOGY

9:00-11:00 A.M.—Grand Rounds

Dr. Daniel B. Kirby

Dr. Donald W. Bogart

(Ward K-1—I & K Building)

##### *Fourth (New York University) Surgical Division*

##### *Adult Surgical Service*

9:00 A.M.—12:00 NOON

Operative Clinic

Drs. Arthur McQuillan, William Hinton, Kenneth Lewis, and Lester Breidenbach

(K-5—I & K Building)

Ward Rounds

Dr. Roland Maier

(Ground L & M and L-1—L & M Building)

##### *Orthopedic Service*

9:00 A.M.—12:00 NOON—Ward Rounds

Drs. Arthur Krida, John McCauley, William Walker, and Albert Schein

(I-6 and I-7—I & K Building)

##### *Children's Surgical Service*

2:00-5:00 P.M.—Operative Clinic

Drs. Fenwick Beekman, Philip Allen, and Charles W. Lester

(K-5—I & K Building)

#### Officers—First District Branch

President.....James G. Morrissey, M.D., Yonkers

First Vice-President.....

.....Scott Lord Smith, M.D., Poughkeepsie

Second Vice-President.....

.....Harold F. Morrison, M.D., Tuxedo Park

Secretary.....I. J. Landsman, M.D., Bronx

Treasurer.....Henry W. Miller, M.D., Brewster

#### Presidents of Component County Societies

Bronx.....Frederick W. Williams, M.D., Bronx

Dutchess.....Harry A. LaBurt, M.D., Wingdale

New York...Conrad Berens, M.D., New York City

Orange.....Walter I. Neller, M.D., Middletown

Putnam...Alexander Vanderburgh, M.D., Brewster

Richmond...D. V. Catalano, M.D., West Brighton

Rockland...Harold S. Heller, M.D., Spring Valley

Westchester.....

.....Merwin E. Marsland, M.D., Mamaroneck

## *Special Notice*

### Members of Eighth District Branch

It has become necessary to change the hotel in which the Eighth District Branch meeting at Niagara Falls will be held on Thursday, October 5, 1944.

Instead of the Hotel Niagara, the place will be the PROSPECT HOUSE—JEFFERSON AVENUE AT SECOND STREET, Niagara Falls, New York.

# Association of Military Surgeons of the United States

Fifty-second Annual Meeting—November 2-4, 1944

Hotel Pennsylvania, New York City

## PROGRAM

### Symposium on Medicine at War

(Georgian Room)

November 2

10 00 A M

Call to Order Col Charles M. Wilson, (MC), USA,  
Chairman

National Anthem Orchestra

Invocation Col J. Burt Webster, Chaplain,  
Second Service Command

Addresses of Welcome

Maj Gen T. A. Terry, Commanding General,  
Second Service Command

Honorable Fiorello H. LaGuardia, Mayor of New  
York City

Dr. Arthur Chace, President, New York Academy  
of Medicine

Dr. Conrad Berens, President, New York County  
Medical Society

Response

Presidential Address

Col. Lucius A. Salisbury, (MC), N Y N G, Inspect-  
tor General Department

Introduction of Distinguished Foreign Guests

Addresses of the Surgeons General

Navy—Vice-Admiral Ross T. McIntire, (MC),  
Surgeon General, U S Navy

U S P H S—Thomas Parran, M D, Surgeon  
General, U S Public Health Service

Army—Maj Gen Norman T. Kirk, (MC), Sur-  
geon General, U S Army

Veterans—Brig Gen Frank T. Hines, Adminis-  
trator, Veterans Administration

Business Meeting 12 00 NOON

2 00 P M - 4 00 P M

*Symposium on War Surgery*

PRESIDING OFFICER

Brig Gen Raymond W. Bliss, (MC), Chief of the  
Operations Service, Office of the Surgeon General,  
U S Army

"Surgery in Forward Military Echelons"

Bureau of Medicine and Surgery, Navy Department, Washington, D.C.

Dr. Chester S. Keefer  
Wade Professor of Medicine, Boston University School of Medicine, Boston, Massachusetts

[Continued on page 2148]

## FOR MEN IN COMBAT

*when the going gets tough*

To save the lives of men in combat through sustaining their mental efficiency by overcoming the symptoms of fatigue, BENZEDRINE SULFATE TABLETS are available for issue in the Armed Forces.

The tablets are issued for combat use under strict medical supervision, and only on those occasions when intense or

prolonged operations, without opportunity for normal rest, are anticipated.

Although this is, of course, a tactical rather than a therapeutic use of Benzedrine Sulfate, the physician will, we believe, be interested to know that this familiar, clinically established drug has such a unique military application.

## BENZEDRINE SULFATE TABLETS

Racemic amphetamine sulfate

SMITH, KLINE & FRENCH LABORATORIES—PHILADELPHIA, PA.

[Continued from page 2146]

*Plastic and Reconstruction Surgery*  
(Parlor 1)

- Lt. Col. James Barrett Brown, (MC), AUS  
In charge of Plastic Surgery, Valley Forge General Hospital, Phoenixville, Pennsylvania

(Continued on page 2150)

Acting against the organisms of secondary invasion, which are responsible for more serious phases of colds,

## ORAVAX

Oral Catarrhal Vaccine Tablet

has proved valuable in rendering colds less severe, and shortening their duration. Clinical reports show

Number of severe colds and total days illness from severe colds in Oravax group only one fifth that in control subjects

—*Journal Lancet* 60 319 324 (1940)

Complete freedom from colds in

81 92% of Oravax group, 12 34% of control group.

—*J M A Georgia* 28 332 334 (1939)

Only one half as much time lost per person per cold in Oravax group as in control group

—*Canad M A J* 41 493 (1939)

Oravax is simple, painless, free from severe reactions. Each small, enteric coated tablet contains fifty billion killed organisms of high antigenicity. Dosage is one tablet daily for 7 days, then one tablet twice weekly throughout season when colds are most prevalent.

Oravax is available at prescription pharmacies in bottles of 20, 50, 100

Trademark Oravax Reg. U.S. Pat. Off.

# In the Management of Asymptomatic and Paretic NEUROSYPHILIS

Statistical studies reveal that approximately thirty per cent of syphilitic patients exhibit abnormalities in the spinal fluid during initial examinations, without displaying clinical symptoms of cerebrospinal involvement. Although adequate routine treatment of early syphilis will prevent the appearance of abnormalities in most cases, the use of Tryparsamide Merck combined with hyperthermy, is suggested in resistant cases.

In incipient cases of dementia paralytica, the use of Tryparsamide Merck, combined with artificial fever therapy, is known to produce varying degrees of symptomatic improvement. While favorable results may not be expected in more advanced cases of general paresis or tabes dorsalis, when treatment is begun sufficiently early and continued over a long period of time, Tryparsamide Merck may arrest deterioration and contribute to the prolongation of life.

The effectiveness of Tryparsamide Merck in the treatment of resistant cases of syphilis probably is due to its unusual ability to penetrate the meningo-vascular barrier of the central nervous system.

## Hospital Charges for X-Ray, Pathology, Anesthesia, and Physical Therapy

*Back in 1926 there was a Court of Appeals' decision in the Sausser case, defining "Roentgenology" as not being of the practice of medicine.*

*Dr. David J. Kaliski, some two years ago, drew up comments on that decision. These are here presented for reference.—Editor*

### Comments on the Decision of Chief Justice Hiscock in matter of *Sausser v. Department of Health, City of New York*, 242 N.Y. 66.

In this action before the Court of Appeals, the proprietor of an x-ray laboratory who was also a chiropractor made an application for a license to operate an x-ray laboratory in the City of New York pursuant to Section 107 of the Sanitary Code, which provides:

"No person shall maintain, operate, or conduct an x-ray laboratory . . . wherein radiographs are taken, diagnoses made, or human beings examined or treated by x-rays, without a permit therefore issued by the Board of Health, or otherwise than in accordance with the terms of said permit and with the regulations of the said Board."

Supplementary to this Section, the Board of Health of the City of New York adopted a regulation providing:

"Every x-ray laboratory shall at all times be in charge of and under the direction of a duly licensed physician or other person whose knowledge, experience, and qualifications to operate and use an x-ray machine are satisfactory to the Health Department."

In the decision the learned Justice stated that there was a provision in the sanitary code and the regulations of the Board of Health to the effect that a person other than a duly licensed physician whose knowledge, experience, and qualifications to operate and use an x-ray machine are satisfactory to the Health Department, "may obtain a license." The petitioner, Sausser, made an application for a permit under these regulations stating, in his petition, that he desired to take radiographs and did not wish to participate in the making of diagnoses or to treat patients. His formal application filed with the Department of Health sustains this claim.

The learned Justice states that the Department of Health and the (lower) Courts have proceeded on an entirely different and inapplicable theory in denying the petitioner's application. They assumed that the petitioner proposed to diagnose and treat conditions of the spine. The correspondence and affidavits submitted conceded the petitioner's experience and skill as an x-ray operator. "They could not well do otherwise in view of the facts set out in his petition," said the Court. "They (the lower Courts and Health Department) assume, however, that the petitioner proposes to diagnose and treat diseases of the spine; that his status as a chiropractor is not recognized as giving him any standing in the medical profession or any qualifications for diagnosing and treating diseases and that, therefore, his application should be denied." The Court held that this theory and view were entirely inapplicable as a reason for denying a permit to the petitioner. The Court accepted his statement that he *did not propose* to diagnose or treat but only to *take* x-ray pictures and *explain* what these pictures show in the way of obvious physical conditions of the spine;

and which pictures would then be used, if at all, by some other person in connection with diagnosis and treatment. Although the Court accepted the statement of the petitioner that he did not propose to diagnose or treat, it did state that he desired to take x-ray pictures and *explain* what those pictures showed in the way of "obvious physical conditions."

I submit that even if the petitioner's statement that he did not desire to diagnose or treat is accepted, the fact that the Court admitted he intended to explain what the x-ray pictures showed in the way of "obvious physical conditions of the spine" is tantamount to diagnosis, under the definition of the practice of medicine under the *Education Law* of the State of New York.

Section 1250 of the *Education Law*, paragraph 7, states: The practice of medicine is defined as follows:

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity, or physical condition."

In order to "explain" what an x-ray film shows the radiologist must, of necessity, be possessed of formal knowledge in physiology, anatomy, and pathology. The explanation of what an x-ray picture shows is, without question, diagnosis under the *Medical Practice Act*. A person, in order to explain what an x-ray picture shows, cannot do so alone without a knowledge of the normal skeleton and functioning of the body organs, and must also be possessed of necessary clinical knowledge and experience in various branches of medical science only gained by years of education and training. In actual practice, an x-ray photograph is of no value to the possessor, even if properly taken, unless he has been trained in the interpretation of such x-ray photograph. The progress of radiology has been such, in the course of the last quarter of a century, that many pathologic conditions can be detected by a person properly educated and trained in this medical specialty.

Many diseases caused by infections, metabolic, hereditary, traumatic, and other causes are disclosed by x-ray examinations. This requires a formal knowledge of the medical sciences which can only be gained by a thorough education and training such as is possessed by a qualified physician.

It is conceded that a lay technician may become expert in the use and application of x-rays in the taking and processing of radiographs or x-ray pictures. In fact, many such lay persons are employed to carry out certain technical examinations

[Continued on page 2154]

TO THE PHYSICIAN WHO SMOKES A PIPE: We suggest an unusually fine new blend—Country Doctor Pipe Mixture Made by the same process as used in the manufacture of Philip Morris Cigarettes

[Continued from page 2152]

with or without the help of the physician and in the processing of the x-ray films. This is the equivalent of the assistance which nurses and laboratory technicians render to qualified physicians in their daily work. But the fact that a person is so technically proficient is not the equivalent to stating that such person, though qualified in a special way or in a limited degree, is qualified without the necessary medical training required of a licensed physician to interpret or explain (diagnose) the findings revealed on an x-ray film. So to hold would be dangerous to the public health and would permit any person technically proficient in the taking or processing of x-ray films other than a duly qualified physician to interpret and explain the findings on an x-ray film, and thus practice medicine.

Many diseases may be detected in their incipency by x-ray examinations by qualified examiners, and to permit an unqualified individual not so educated and experienced to practice under the exceptional provisions of the regulations set up by the Department of Health would be inimicable to the welfare and well-being of the people of this State.

The statement of the learned Justice that "Certainly taking an x-ray photograph is not diagnosis or treatment," while in itself correct, is contrary to all experience, if the taking of such film is coupled with the right to explain the findings of such picture. The explanation of what an x-ray photograph shows is a vital part in the total diagnosis of many conditions confronting the physician.

The Justice further states that "An x-ray photograph would not show much to an ignorant and inexperienced eye. To one who is skillful and has understanding it would show a certain location or external condition of the spine, for instance, and I do not think that the explanation of what was thus shown would go beyond the limits of x-ray photography any more than the explanation of what appeared to be a blotch or shadow upon an ordinary photograph would go beyond the limits of ordinary photography."

The Justice was undoubtedly confused or ignorant as to the purpose and value of an x-ray examina-

tion as compared with the reading of an ordinary photograph. No lay person can be skillful and have understanding in order to determine the "location or condition of the spine" nor give an explanation of "the condition" present, any more than a person looking at an ordinary photograph would be able to determine what certain abnormalities on the photograph meant in terms of medical diagnosis. An x-ray film may be of no value whatsoever even to a licensed physician who is not also qualified in interpreting the findings and evaluating them. The purpose of the physician in referring a patient for x-ray examination is to obtain a proper diagnosis based upon the skill and experience of the radiologist. Even qualified physicians recognize their limitations and depend upon the expert experience and training of the radiologist in taking and interpreting x-ray films and in establishing a diagnosis either by confirmation or the clinical findings or their negation. In the light of clinical medical experience a negative x-ray finding may be as important as positive findings.

Again, the mere description of a shadow or line in an x-ray film may be of little value to an inexperienced person or unqualified practitioner. It may mean a fracture or a healed fracture or a congenital condition or some other disease or condition and may require expert knowledge for proper interpretation. Without proper interpretation, no matter how skilled in the technic of taking and processing an x-ray film a person may be, there is little or no value to the procedure; indeed, there is the potential danger that an incipient lesion detrimental to the health of the individual may be overlooked or that an actual lesion in the shape of a break in continuity of a bone may be attributed to force or trauma when in fact there may be another underlying pathologic condition, such as malignancy or syphilis.

The decision in the Sausser case is an anachronism and not in accordance with present-day concepts of the expert nature of medical diagnostic radiology, which is without doubt the practice of medicine as defined in the Medical Practice Act of this State.

DAVID J. KALISKI, M.D.

### Dewey Names Board to Study Medical Care

GOVERNOR Thomas E. Dewey appointed on September 5 the members of a temporary commission, created by the 1944 Legislature, on his recommendation, to make necessary studies "in order to devise programs for medical care for persons of all groups and classes in the State."

The aim is to provide proper medical care for the needy at public expense, without embracing elements of socialized medicine. This was stated by Mr. Dewey in a memorandum accompanying his appointments.

"Of the many fields in which the social services extended by the state and local governments have been so progressively extended," he said, "the field of medical care has received least attention."

"The program has been delayed in solution by the difficulties in finding a middle ground between the extreme views of those who desire to socialize the medical profession and those who oppose all broadening of medical care."

Dr. Basil C. MacLean, of Rochester, until recently a lieutenant colonel in the Army Medical Corps, was appointed by the Governor to head the commission as chairman. Assemblyman Lee B. Mailer,

Republican, of Cornwall-on-Hudson, was named vice-chairman.

Nine other members were appointed by the Governor. They are the Rev. John J. Bingham, assistant secretary of the Catholic Charities of the Archdiocese of New York; Dr. Lucien Brown, formerly of Harlem Hospital and now connected with Sydenham Hospital, both in New York City; Dr. Robert Levy, professor of clinical medicine in the College of Physicians and Surgeons of Columbia University; Garrard B. Winston, New York lawyer, Under Secretary of the Treasury from 1923 to 1927; Miss Agnes Gelinap, professor of nursing in the Skidmore College Department of Nursing; Dr. George MacKenzie, of Cooperstown, physician-in-chief at Mary Imogene Bassett Hospital there; Dr. Herman Gates Weiskotten, of Syracuse, member of the New York State Public Health Council; Miss Ruth Hall, of Buffalo, chairman of procurement and assignment for the New York State Nurses Association; and Miss Marion Sheehan, of Albany, director of the Division of Public Health Nursing of the State Health Department.

There are four members from the Legislature, Senators Lester Baum, Manhattan (Republican), and Lazarus Joseph, Bronx (Democrat), and Assemblymen Mailler and Leonard Farbstein, Manhattan (Democrat). The State Commissioners of

Health, Social Welfare, and Mental Hygiene are ex-officio members.

Governor Dewey's announcement followed closely on the announcement by Mayor F. H. LaGuardia of the incorporation of his health-insurance plan for all New Yorkers earning up to \$5,000 a year.

### Medical Center Here to Get Mental Clinic

THE Columbia University Department of Psychiatry will open a psychoanalytic and psychosomatic clinic for training and research this month at the Columbia-Presbyterian Medical Center, Dr. Willard C. Rappleye, dean of the faculty of medicine, announced.

Physicians who are graduates of approved medical schools and who have completed approved hospital internships of at least a year will be admitted to the three-year course of resident graduate training.

The course will include lectures, seminars, clinical conferences, and supervised clinical work in the psychoanalytic and psychosomatic fields, combined

with two years of resident graduate study in other branches of psychiatry. Emphasis will be placed on related basic medical sciences. The degree will be Doctor of Medical Science.

The clinic will be supervised by Dr. Nolan D. C. Lewis, executive officer of the Department of Psychiatry at Columbia and director of the New York State Psychiatric Institute and Hospital. Dr. George E. Daniels was named chief of psychosomatic service. Dr. Sandor Rado will be director of the clinic and chief of psychoanalytic service. Both are clinical professors of psychiatry. Assistants will include Drs. David M. Levy and Abraham Kardiner.

### Says Evils of Political Medicine Are Shown by New York State Setup

THE management of the Department of Mental Hygiene of the State of New York provides an example of what the American people may expect if political medicine ever takes over general medical care in this country, the *Journal* of the American Medical Association declares in its September 2 issue. The *Journal* says:

"When an epidemic of amebic dysentery occurred in the Creedmoor State Hospital in New York in March, 1943, Gov. Thomas E. Dewey appointed a commission to investigate the management and affairs of the Department of Mental Hygiene of the State of New York and the institutions operated by it.

"That report, which has just been made available, emphasizes again the defects that seem inseparable from political medicine. In 1942 New York mental hospitals were caring for 83,053 patients at an annual cost of \$30,474,048.08. The commission found everywhere signs of inadequate examination of mental defectives, unsatisfactory recording of physical conditions on admission, and lack of professional care, owing largely to the use of an undermanned professional staff. 'The emphasis

in all the institutions has been on administration at the expense of clinical medicine,' says the report. This is the familiar criticism of all types of political medicine. In the mental hospital service in New York State advancement went to 'careerists' and not to the psychiatrists of wide experience and knowledge. New methods of treatment such as shock and physical therapy disturbed the routine of the institutions and were therefore neglected. The report indicates that this service had not attracted competent physicians. Nurses were insufficient in numbers, and defective in quality and were assigned to administrators and their families rather than to patients. The diets were monotonous and were not supervised by dietitians. Research and education were neglected or isolated in bureaucratic subdivisions apart from the treatment of patients. Here were all the apparently inevitable evils of mass medical treatment. Here were all the faults that usually accompany compulsory political care. Here, in miniature, is a picture of what the American people may expect if political medicine ever takes over general medical care in this country."

### County News

#### Albany County

Dr. Elizabeth M. Gardiner, director of the State Health Department's Division of Maternity, Infancy, and Child Hygiene, retired from state service, effective August 31.

Dr. Gardiner has devoted practically her entire professional career to the promotion of maternal and child health, the greater part in the service of New York State. From 1919 until the fall of 1923 she was director of the Division of Child Welfare in the Rhode Island Department of Health. During the past twenty-one years she has been associated continuously with the New York State Department of Health, first as associate director of the Division of Maternity, Infancy, and Child Hygiene and since 1926 as its director. Under her leadership, there was notable expansion in medical and nursing activities for the health protection of mothers and young children and in the fields of nutrition education and dental care. She was responsible for the develop-

ment in New York of official programs implemented through federal funds allotted to the several states for the extension of maternal and child health services under the Sheppard-Towner Act and the Social Security Act.

During Dr. Gardiner's administration, the publications issued by her division on maternity and infant care have become standard works of reference in homes all over the State. Thousands of expectant mothers and mothers of young children, many of them referred by their family physicians, have learned to look upon her and her staff as friendly counselors to whom they may turn for information and advice on such matters as preparation for maternity and care of their babies. Outstanding among the services developed under Dr. Gardiner's direction have been those in the field of nutrition.

Coincident with the sharp nationwide drop in maternal mortality during the period 1933-1940,

[Continued on page 2158]

## TO SHORTEN THE PERIOD OF *Convalescence*

More than so-called tonics and restoratives, Ovaltine can materially shorten the period required for the return of strength and vigor following recovery from infectious or prolonged illnesses. During the acute stages of febrile diseases, when the patient's nutritional intake is low and requirements higher than normal, many metabolic deficits are developed. These can be made good only by a high intake of essential nutrients during the recovery period,

for only after these deficits are wiped out can former strength and well-being return.

Ovaltine offers many advantages as a nutritional supplement to the diet of convalescence. This delicious food drink is rich in minerals, vitamins, and biologically adequate proteins. Its appealing taste invites consumption of three or more glasses daily. Its low curd tension encourages rapid gastric emptying, an important factor in maintaining good appetite.

THE WANDER COMPANY, 360 North Michigan Avenue, Chicago 1, Illinois

(Continued from page 2156)

the New York State rate decreased by 52 per cent, the degree of improvement having been greater than in most of the other states. The 1943 rate (20 per 10,000 live and stillbirths) was the lowest ever experienced in this State. While many factors contributed to this downward trend, as well as to the marked decline in infant mortality, the advance made may be attributed in part to efficient administration of progressive maternity and child health services.

Dr. Gardiner has made many warm friends, both within the Department and throughout the State, who extend to her hearty wishes for happiness in her retirement. She plans to remain in Albany and the Department looks forward to her continued interest in its work and to the opportunity of her counsel in problems relating to the health of mothers and children.—*Health News, Sept. 11, 1944*

### Erie County

The following excerpt is from the *Buffalo News* of August 25, 1944:

A discovery by two University of Buffalo and Meyer Memorial Hospital physicians which opens a new and long-sought approach in the war against tuberculosis is announced today in the scientific journal, *Science*.

The development, a green mold which inhibits the growth of tuberculosis germs, was found by accident in an icebox in the U. B. Medical School while the two investigators were seeking a mold which might be effective against tuberculosis.

As a result of their discovery, Dr. David K. Miller, chief of medicine at the hospital and professor of medicine in the Medical School, and Dr. Albert C. Reke, resident in medicine at the hospital and hospital assistant on the school's staff, have received a \$7,500 grant from the Office of Scientific Research and Development to continue the research.

The mold probably is akin to penicillin and was discovered in almost the same manner, but it is only a distant relative, for penicillin has thus far been unsuccessful in fighting tuberculosis. Preliminary experiments have revealed that the new mold impedes the growth of tuberculosis germs both in germ cultures and in experimentally infected guinea pigs.

It was a germ culture that brought about the discovery. Drs. Miller and Reke were surprised one day to find that the culture of tubercle bacilli stored in an ice-box had been overgrown by the strange mold.

They took subcultures of the mold and tested them on other cultures of the deadly germ. At room temperature, the fungus growth feasted on the germ cultures—even growing faster than on other kinds of food.

Thereupon the physicians studied its effect on tuberculosis in animals. They took recently isolated, rapidly growing strains of human-type tubercle bacilli and mixed suspensions of these with suspensions of the mold. They permitted the mixture to stand at room temperature for twenty-four to forty-eight hours.

Then they injected the resulting concoction into guinea pigs. In thirteen experiments seven guinea pigs failed even to be infected by tuberculosis, although normally such injections of the bacilli would have been fatal. (Six guinea pigs did die.) All but one of the control animals that had been injected with untreated germs perished. Examination of the culture tubes indicated the mold had checked growth of the tubercle bacilli without destroying them, for even after several months the bacilli were found still present in the tubes. This is like the action of penicillin and the sulfa drugs, which inhibit growth but don't kill germs.

The doctors found that the mold is sufficiently potent so that its suspensions destroy the potency of tuberculin within two hours. Tuberculin is a sterile liquid which has as its basis the poison which tuberculosis germs produce.

Experiments using extracts of the mold and of the fluid produced by centrifuging it are now in progress in an effort to isolate the germ-inhibiting factor in the mold. The doctors would not comment on these studies.

Although other investigators have reported no success thus far against tuberculosis with penicillin, the mold product which has been so remarkably effective against a wide variety of other bacterial diseases, a report last month from the United States Naval Hospital at Corona, California, said penicillin had been used effectively in two cases of human empyema. This is a tuberculosis complication, a pus formation caused by invasion of streptococci and staphylococci in the covering of tubercular lungs.

### Jefferson County

The regular monthly meeting of the county

society was held September 14 at the Black River Valley Club.

Dinner was served at 6:30 P.M. "Malaria and the Dysenteries" was the title of an address by Dr. Stockton Kimball, assistant in medicine, University of Buffalo College of Medicine.

Announcement was made that the Jefferson-Lewis Medical Care Plan of the Farm Security Administration was withdrawn, as of September 1, 1944. Membership cards will therefore no longer be honored.

### Monroe County

Drs. S. W. Clausen, A. B. McCoord, and C. P. Katsampes, of the departments of pediatrics and bacteriology at the University of Rochester, have developed a new technic of infecting rats and mice with tuberculosis. They pointed out at the meeting of the American Chemical Society, which was held in New York City in September, that one of the serious handicaps of science in the search for a drug that would conquer tuberculosis has been the lack of an animal in which the disease could be produced in a form resembling that found in man.

The three doctors found that they were able to infect rats and mice by putting tubercle bacilli mixed with salt water into their nostrils. When the rodents breathed the germs were drawn into their lungs. Two weeks later forty of the rats began to die. The disease appeared to have remained localized in the lungs, so the investigators believe their method of infecting rats and mice will aid in the study of the disease.\*

### Montgomery County

Dr. William J. Ryan, director of the Montgomery Sanatorium since December 3, 1942, has submitted his resignation to the Board of Managers of the Sanatorium, effective September 30.

Dr. Ryan plans to enter private practice in Syracuse, his home city, as soon as his successor is named.

Although the names of several physicians have been submitted as possible successors to the director of the tubercular sanatorium, no action has yet been taken by the board of managers. The resignation of Dr. Ryan was accepted with regret, and members of the board expressed their sense of loss of his leaving, in view of his extensive accomplishments in the eradication of the disease in the county.\*

Dr. Norbert Fethke announces the opening of his office for the practice of the medical profession, limited to the care and treatment of diseases of the eye, at 54 Church Street, Amsterdam.

Dr. Fethke was born in Poland and received his early training in the field of chemistry at Danzig. Later he continued these studies under one of the greatest scientists of the time, Dr. Fischer, who was awarded the Nobel prize in 1929.

In the year 1931 Dr. Fethke was accepted by the Pasteur Institute in Paris. He received his medical education at the University of Paris and graduated in natural sciences at the Sorbonne.

For several years prior to the war Dr. Fethke was connected with the Pasteur Institute and attended the well-known clinics in Paris, like Lariboisière and the eye clinic at Hotel Dieu. He is the author of several medical publications.

Dr. Fethke served with the Polish army at the

URTICARIA.

(Half strength available for children in capsules only)

**Supplied:** Capsules for prompt and symptomatic relief. Tablets, enteric-coated, for delayed action and prophylactic relief.

**Therapy:** One capsule and one tablet taken at bedtime are effective in controlling symptoms for twelve to fourteen hours,\* assuring uninterrupted sleep. Repeated at morning helps prevent attacks during the day and completes a cycle of twenty-four hours of relief. The capsule gives relief almost instantly and is effective for 3-5 hours. The tablet, beginning absorption three to five hours after administration continues the relief for another 3-5 hours, or more.

front in France. After passing through Spain and Portugal he arrived in the United States in 1942.

In this country he was engaged in research at Yale University, New Haven, Connecticut, and later attended the eye clinic in the Polyclinic Hospital in New York. At present he is associated with the Albany Medical College.\*

#### Nassau County

The September meeting of the county society took the form of a golf tournament and stag dinner at the Wheatley Hills Golf Club in East Williston, Long Island, on Wednesday, September 20.

#### New York County

Two New York medical men, Dr. Colter Rule and Dr. Axtell E. Johnson, both of the College of Physicians and Surgeons of Columbia University, were "victims" of voluntary experiments conducted in high-altitude flying when both contracted tuberculosis as a result of the reopening of long-healed tuberculosis scars, it has been revealed nationally.

A report of the experiment was made to the Aero Medical Association of the United States at St. Louis September 6 by Dr. Johnson, who has recovered from the disease, and by Dr. Alvan Barach, director of the experiments for Columbia.

The Columbia men were studying high-altitude flying in conjunction with "bends," a distressing affliction of fliers, when they discovered that the 42,000-foot altitude would reopen old tuberculosis scars. Both Dr. Johnson and Dr. Rule had voluntarily subjected themselves to tests in steel decompression chambers for half-hour periods.

The result of the discovery probably will be the exclusion from flying schools of all persons with spots on their lungs, even if long healed, the doctors suggested.

On September 1, 1944, Mr. James E. Bryan assumed his duties as Public Relations Officer and Editor of the *Journal* of the Medical Society of the County of New York. The Publication Committee and the editorial staff extend to him a cordial and hearty welcome.

Mr. Bryan begins his new work in New York County after twelve years as Executive Secretary of the Westchester County Medical Society and Managing Editor of its *Bulletin*.

Mr. Bryan has been a member of the board of directors of the Westchester Tuberculosis and Health Association for the past ten years, serving as its president in 1940 and 1941. During the war

period he has served as deputy director of Emergency Medical Service in the Westchester Office of Civilian Protection and as secretary of the Medical Care Subcommittee of the Disaster Relief Committee of the Westchester Chapter, American Red Cross. He is a member of the Health Advisory Council of the Westchester Cancer Committee, and the Westchester Nursing Council for War Services. He comes from a medical family, his father being a physician still in active practice in Asbury Park, New Jersey, and he has the imagination, the creative spark, to render invaluable service to the county society.

The New York Diabetes Association, Inc. held an open meeting on September 28 at 8:30 p.m. at Blumenthal Auditorium, Mt. Sinai Hospital, in New York City.

Herman O. Mosenthal, M.D., Chairman, Committee on Research, presided over the meeting. The papers which were read were "Alloxan Diabetes," by Dr. Martin G. Goldner, assistant professor of medicine, University of Chicago, and "Histology of the Normal and Diseased Pancreas," by Dr. George Gomori, assistant professor of medicine, University of Chicago. Dr. Paul Klemperer, pathologist, Mt. Sinai Hospital, discussed the papers.

The meeting was open to all physicians and medical students.

#### Sr. Lawrence County

Sixty persons attended a luncheon and meeting of the county society at the Potsdam Club on August 16. Dr. Orren D. Chapman, of Syracuse University, addressed the group on the methods which may be used in treating soldiers who will return from the tropics with various tropical diseases.\*

#### Steuben County

A joint meeting of the county society and the county bar association was held September 14 at the Hotel Sherwood in Hornell.

After luncheon at 1:00 p.m. a scientific program was presented at 2:00 p.m. Dr. Philip Levine, director of the Biological Division, Blood Testing Laboratory, Ortho Research Foundation, Linden, New Jersey, spoke on "The Medicolegal Consideration of Blood Groups in Paternity Cases," and W. Earle Costello, of Corning, spoke on "The Legal Aspects of Paternity Cases."

A business session followed immediately after the scientific session.

## Nurse Recruitment Quotas for 1944 Set

STATE quotas for Army and Navy nurse corps recruitment for the period ending December 31, 1944, released to State Committees for the Procurement and Assignment of Nurses, have been set generally at a figure equivalent to one-third of the number of student nurses graduating this year in each state, the War Manpower Commission announced on August 10.

The state quotas, WMC said, are to meet the increasing demands of the armed services for nursing services and to furnish replacements on the battlefields and in military and naval hospitals in this country. Approximately 6,000 of the new nurses will be recruited for the Army and 3,000 for the Navy.

According to the nursing section of the Procurement and Assignment Service of WMC, quotas are less than one-third of anticipated graduates in states having a nurse shortage. States which failed to meet quotas for the first six months of this year have

been assigned higher quotas for the period ending December 31.

Thirty-seven states met their quotas for the first six months, bringing the total number of graduate nurses accepted for military service for this period to 7,869. The goal was 8,000.

The actual recruiting of nurses for the Army and Navy is conducted by American Red Cross recruitment committees. All of the nurses recruited by these committees will come from the pool of graduate nurses declared available for military service by state and local procurement and assignment committees that classify all graduate nurses either as available for military service or essential in their present positions.

The large majority of nurses assigned to military service during the next six months will be new and recent graduates, many of whom have completed their nursing studies under the U.S. Cadet Nurse Corps program, WMC said.

## Hospital Librarians to Have Organization

LIBRARIANS in hospitals, who up to now have had no special provisions made for their advancement and organization, now have their choice of two such arrangements.

The Special Libraries Association, at its recent conference in Philadelphia, June 19 to 21, formed a group for hospital and nursing school librarians. Ruth Tews, head of the hospital library service of the St. Paul Public Library, was appointed chairman.

All persons who are interested in receiving the news letter from this group are invited to write Miss Tews.

The group is designed to "give all librarians working in hospitals opportunity for active participation in the national development of their work, in determining standards, in considering publications and in extending their work." Librarians from Chicago,

New York, Minneapolis, and St. Paul petitioned for this action.

At the same time a petition was circulating among hospital librarians for the formation of a hospital libraries division in the American Library Association. At present, these librarians have only a round table in the A.L.A. A division has almost complete autonomy, elects its own board and officers, has representation on the A.L.A. council and receives for its own uses 20 per cent of the A.L.A. dues of its members.

If a division is formed it would have sections for hospital, institutional, medical, and nursing school libraries and for others if needed. The petition was circulated by Mrs. Glyde B. Nielsen, secretary-treasurer, A.L.A. Hospital Libraries Round Table. Mrs. Nielsen is with the Minneapolis Public Library.—*The Modern Hospital*, August, 1944

## Hospital Projects Recommended in Twenty States

HOSPITAL projects in twenty states to provide 16,000 additional beds, to cost \$70,000,000, have been recommended to the Federal Board of Hospitalization by the Veterans Administration.

The new beds would include 5,000 for neuropsychiatric patients, 3,000 for tuberculosis victims, and 8,000 for general medical and surgical cases. The announced program is the first in the \$500,000,000

hospital setup authorized in the "G.I. Bill of Rights" law. The new hospital facilities will be located in New Hampshire, Rhode Island, Delaware, Virginia, Florida, Michigan, Kentucky, Louisiana, Mississippi or Alabama, eastern Kansas or northern Missouri, eastern Montana or western North Dakota, Colorado, California, Texas, Washington, New York, Georgia, Ohio, Pennsylvania, and Illinois.—*J.A.M.A.*, Aug. 19, 1944

## Nurses Lack Opportunity to Learn Clinical Aspects of Nursing

THAT the 100-daily-average-patient criterion does not necessarily provide students adequate opportunities for learning clinical aspects of nursing is brought out in the article, *Clinical Facilities*, in the August, 1944 *American Journal of Nursing*.

The article is based on a study of clinical facilities in the home-hospital of 1,047 schools of nursing by

the Department of Studies of the National League of Nursing Education.

The article points out that, although schools of nursing in 1943 were connected with larger hospitals than they were in 1939, 25 per cent of the schools were connected with hospitals having a

daily average of only 68 patients or fewer, while the home hospitals of forty-eight of the schools had a daily patient census of less than 30.

The median number and the range of patients on the four basic services in the hospitals reporting are as follows:

Clinical Service	Patients on Service		
	Median	Low	High
Pediatric	11	1	320
Medical	29	3	1,025
Obstetric (mothers and infants)	38	2	448
Surgical	47	4	877

## Improvements

Purchase of an iron lung for Ideal Hospital in Endicott by the Broome County Chapter of the National Foundation for Infantile Paralysis was announced on August 1 by Thomas H. Fogarty, president of the Broome Chapter.

A new iron lung has also arrived in Ithaca for use at the Ithaca Reconstruction Home.

It was presented to the people of Tompkins County by the Ithaca Aerie 1253, Fraternal Order of Eagles; Ithaca Lodge 636, BPO Elks; Ithaca Chapter 666, Loyal Order of Moose, and Finger Lakes Post 961, Veterans of Foreign Wars.\*

Nearing completion is the new Deaconess Hospital, Buffalo, addition, constructed under a \$486,000 Lanham Act grant. The work will probably be finished about November 1, according to Supt. Henry T. Brandt. The addition will increase the capacity of the hospital to 350 beds for adults and 101 for infants.\*

Downtown Hospital in New York City, in order to be completely modernized and streamlined, was temporarily closed, it was announced by A. O. Davidsen, administrative director; it reopened on September 12 with ceremonies including a parade.

The institution, formerly the Broad Street Hospital, was opened September 17, 1917, to serve the downtown financial and waterfront districts.\*

Construction of its own sewage disposal plant, to serve the more than 2,000 patients and personnel

which will be housed at the U.S. Veterans Facility in Canandaigua by next year, will be started by the Government this fall.\*

Completed in ten days, at the rate of one a day ten hospital recreation rooms in the Mitchell Field Base area were recently furnished by Nassau women serving as volunteers of the Red Cross Camp and Hospital Committee of Nassau, Mrs. Harry I. Nicholas, chairman, announced.\*

The Waterloo Memorial Hospital has a new operating-table light, which was purchased from a fund started by the Waterloo and Seneca Falls Nurses Association about three years ago and added to by other individuals and organizations in Waterloo until the necessary amount of about \$780 was raised.\*

An insufflation unit used to regulate the amount of oxygen administered to a patient has been presented to the Herkimer Memorial Hospital by the William Hempstead Post of the Veterans of Foreign Wars, Ilion.\*

Uticans recently donated eighteen electric fans to Rhoads General Hospital. A drive to obtain two hundred fans has been in progress for several weeks.\*

## At the Helm

Promotions of six officers among Rhoads General Hospital personnel were announced in Utica on August 9 by Col. A. J. Canning, commanding officer.

Promoted from captain to major were:

Carl M. Guymor, Medical Administrative Corps, post adjutant. Major Guymor has completed twenty-eight years of military service, and has been stationed in Fort Dix and in the Philippines. He came to Rhoads Hospital from Halloran General Hospital, March 25, 1943.

Louis E. Marshall, Medical Corps, Brooklyn, chief of laboratory service at the hospital since October 9, 1943. Major Marshall was graduated from the New York University College of Medicine in 1936.

Carlos M. Julia, MC, Hato-Rey, Puerto Rico, attached to the surgical service and consultant of penicillin treatment. He was graduated from the

University of Paris School of Medicine in 1935, and has been at Rhoads since April 4, 1943.

Promoted from first lieutenant to captain was:

Edward Kezur, MC, Toledo, Ohio, attached to the neuropsychiatric section. He was wounded in action at Attu, and has received the Purple Heart award. Captain Kezur has been at Rhoads since last February 13.

Promoted from second lieutenant to first lieutenant were:

Herman L. Leyton, Signal Corps, New York City, attached to the laboratory service. Lieutenant Leyton was born in China, was graduated from Long Island University in 1941, and has been at Rhoads since last November 21.

William M. Ganey, MAC, Dunkirk, assistant post medical supply officer. Lieutenant Ganey enlisted in the Army February 25, 1942, and was commissioned July 7, 1943, at Camp Berkeley, Texas.\*

# Pediforme

## FOOTWEAR

### for FLAT-FEET

The family physician, in health examinations, will not over-look examining the feet of babies and growing children for evidence of flat-feet through heredity tendencies or other causes—and will naturally prescribe measures for correction.

Proper shoes are essential to supplement the doctor's own treatments—but a proper source of supply is essential, too, and the patient of any age-group should be directed to competent and trustworthy fitters of correctly designed shoes of scientific construction. Pediforme footwear have the qualities desired by the doctor and the attractiveness so vital to the sensitive patient.

THE DOHO CHEMICAL CORPORATION  
 New York - Montreal - London

[Continued from page 2164]

Thomas T. Murray, superintendent-administrator of White Plains Hospital for four years, has resigned, the resignation to become effective on September 30.

Mr. Murray went to the White Plains institution from Albany Memorial Hospital, where he served as superintendent for fourteen years.

Mr. Murray is a native of Scotland. He came to Canada in 1911 and served overseas with the Canadian Expeditionary Force in World War I.

After the war Mr. Murray became superintendent of a hospital in Saskatoon, Saskatchewan. Later he became director of the General Hospital at Knoxville, Tennessee.

Mr. Murray is a former president of the State Hospital Association.\*

Dr. David W. Park has resigned as superintendent of Potsdam Hospital, Potsdam, New York, to join the staff of the American College of Surgeons.

David M. Dorin, formerly assistant director of Beth Israel Hospital, New York City, has been chosen as executive director of Sydenham Hospital, New York City. Last December the hospital was reorganized on a fully interracial basis, with a board composed of six Negro and six white trustees. The interracial policy is also followed in the medical, nursing, administrative, and other staffs. It is believed to be the first voluntary hospital to inaugurate the interracial idea.

Frances Chappell, former superintendent at North Country Memorial Hospital, Glen Cove, New York, has been named head of Memorial Hospital, Owosso, Michigan.

Dr. George W. Cottis, of Jamestown, past-president of the Medical Society of the State of New York, has been appointed by Governor Dewey to the Board of Visitors for the State Institute for the Study of Malignant Diseases at Buffalo.

Dr. Cottis was one of five named to the board. The other four are Alfred H. Kirchhofer, Buffalo; Dr. Walter L. Machemer, chief of the surgical department of the Buffalo Children's Hospital; Dr. John J. Morton, chief surgeon of Strong Memorial Hospital, Rochester; Dr. James B. Murphy, New York City, a member of Rockefeller Institute; and Dr. Frederick S. Wetherell, surgeon of the Memorial and St. Joseph's Hospitals, Syracuse.\*

Dr. Richard H. Freyberg, assistant professor of internal medicine and in charge of Rackham Arthritis Research at the University of Michigan School of Medicine, Ann Arbor, has been appointed chief of the department of medicine and pediatrics at the Hospital for Special Surgery in New York City, effective September 1. Dr. Freyberg will succeed Dr. Carlisle S. Boyd, who has been appointed to the board of consultants of the hospital.

Judge George M. Penney of Oswego, Oswego County surrogate, was elected president of Oswego Hospital at a meeting of the board of trustees on July 10.

Judge Penney succeeds Miss Anna W. Post, who served during the past year, but who, because of illness, could not continue in office. Mrs. Jermyn J. Downey was elected second vice-president and Chester M. Jermyn, secretary. A first vice-president is to be appointed.\*

Miss Isabelle V. Cameron has assumed her duties as superintendent of the Cohoes Hospital.

Miss Cameron went to Cohoes from New York City, to succeed Miss Margaret Smylie, who has resigned.

A native of Scotland, Miss Cameron trained at Mountinside Hospital, Montclair, New Jersey. She last served as superintendent at Commonwealth Hospital, Pittsfield, Illinois.\*

Andrew W. Patrick, member of the Herkimer town council, has been named district manager for the Blue Cross Hospital Plan, Inc., succeeding J. Kenneth Young.

Mr. Patrick will have charge of hospital-plan offices in Herkimer, Ilion, and Little Falls.

Mr. Young has been transferred to the northern part of the state.\*

Sister St. Edward, mother general of the Grey Nuns of the Sacred Heart, Melrose Park, Pennsylvania, has appointed Sister Mary Carmen superintendent of the A. Barton Hepburn Hospital in Ogdensburg, to succeed Sister Mary Monica, whose six-year term has expired. Sister Monica has been transferred to Champlain Valley Hospital in Plattsburg.\*

Dr. Clement J. Handron, of Troy, was appointed to succeed Dr. Vincent Mazzola, of New York City, on the medical Committee on Grievances of the State Board of Medical Examiners, at a meeting of the State Board of Regents held in New York on July 21.\*

## Newsy Notes

Manhattan's thirty-four voluntary hospitals, members of the Greater New York Hospital Association, nearly tripled their quota in the Fifth War Loan, John F. McCormack, chairman, and Mrs. Donald B. Woodward, cochairman of the Hospital Division, War Finance Committee for New York, have announced.

The quota accepted by the group at the beginning of the drive was \$3,500,000. The final figures show an over-all total of \$9,256,640, or 264 per cent of quota.

[Continued on page 2168]

## EXTERMINATING COSTS

A statistician has computed that it costs the U. S. fifty-five thousand dollars to exterminate one Nazi on the ground, and it is cheaper by \$11,000 to bring down one of Goering's planes.

The cost, continues the expert, required to kill one soldier in this war would have destroyed 66,000 men in the days of Julius Caesar. It cost but 70

bargain days.

honor of put-

is. The price

\$3,000 in the

days of his aspirations to rule the world. The American Civil War raised the ante to \$5,050 per fighting man. Multiply that figure by four-plus and you will have the expense for killing a Hun in World War I.

In the twenty-odd years since the last war, the high cost of killing enemies has more than doubled. There is an old saying that "war doesn't pay"—but apparently everybody else does, even the Germans spend about the same amount every time they shoot a Russian, a Briton, or a Yank.

But, the III Reich is getting off cheaper than we are for they are killing less Yanks than the fatalities they are suffering. Which is as we would have it regardless of cost in dollars

## THE END OF DENTAL DECAY?

With some dental experts of an opinion that a real decay preventive has been found—science hopes

Deaf Smith County, Texas, may go down in history as the prophetic harbinger of sound teeth for all mankind. This is one place in the U. S. A. where hundreds of persons don't know what it is to writhe in a dentist's chair, and where there was an average of only one bad tooth per child among 810 school children examined. The average in less fortunate localities would run from 5 to ten

An explanation of this phenomena may be in the discovery that there are 2.5 parts of fluorine to 1,000,000 parts of water in that locality—five or six times as much as found in other communities. In laboratories it has been found that fluorine acts to prevent tooth decay—either by retarding the formation of certain harmful acids in the mouth or by making teeth much less soluble in acids that exist, or through both actions.

The ten-year tests on the populations of Newburgh and Kingston, N. Y., and Brantford, Ontario, may eventually be instrumental in putting an end to at least 90 per cent of all tooth decay. Here 96,000 controls will prove whether fluorine added

against disease, contends that while added fluorine it may still il-calculated visit to the dentist three times a year, but all he each tooth with a

hasn't offered 100 per cent anti-decay defense, but Dr. Bibby expects greater results from the technique. Some may insist that a drink of prevention is better than three visits to the dentist—if it becomes as simple as that, however, the good old toothbrush will still be an asset for a beautiful smile, even when the last drill and last forceps have rusted.

# Effective Convenient Economical

THE effectiveness of Mercurochrome has been demonstrated by more than twenty years of extensive clinical use. For professional convenience Mercurochrome is supplied in four forms—Aqueous Solution in Applicator Bottles for the treatment of minor wounds, Surgical Solution for preoperative skin disinfection, Tablets and Powder from which solutions of any desired concentration may readily be prepared.

## Mercurochrome

(H. W. & D. brand of merbromin,  
dibromoxymercurifluorescein-sodium)

is economical because stock solutions may be dispensed quickly and at low cost. Stock solutions keep indefinitely.

Mercurochrome is antiseptic and relatively non-irritating and non-toxic in wounds.

Complete literature will be furnished on request.

**HYNSON, WESTCOTT  
& DUNNING, INC.**  
BALTIMORE, MARYLAND

[Continued from page 2168]

gestion for a pipette washer to be used in the laboratory will effect an annual saving of about \$330 to the hospital.

The suggestion program at Finney General Hospital is part of the national drive for suggestions that will speed production, save time and money, and speed up efforts to win the war. \*

. . .

The Half Moon Hotel at Coney Island was commissioned as a Naval Convalescent Hospital on August 30 and Comdr. Earle P. Huff was designated its Medical Officer in Command, at ceremonies on the sundeck of the fifteen-story, 303-room building that faces the ocean at the entrance to New York Harbor.

Rear Admiral Edward U. Reed, Medical Officer of the Third Naval District, read the orders commissioning the hospital. \*

. . .

Over 2,000 additional persons enrolled in the Chautauqua Region Blue Cross program during the first six months of 1944, according to Robert E. Johnson, executive director. This brings the total

in Chautauqua County to approximately 18,500, Mr. Johnson said.

. . .

A campaign to raise \$350,000 for Sydenham Hospital, in New York City, began on July 26, with a luncheon at the Hotel Roosevelt. The hospital was the first voluntary hospital in the country to include both Negroes and whites among its doctors, nurses, patients, and trustees.

Eduard C. Lindeman, professor of social philosophy at the New York School of Social Work, Columbia University, was the principal speaker. "Disease knows no color lines," he said. "Bacteria don't discriminate."

"There it stands," he said of the hospital, "in the heart of the densest Negro population in the world, and there is no intimation of racial friction. It is one of the most meaningful experiments in racial behavior I have seen on the continent."

. . .

Carl M. Metzger, executive director of the Hospital Service Corporation of Western New York, has just issued a report showing that membership in the local Blue Cross Hospital Plan jumped to an all-time high of 370,000 during the first six months of this year. \*

#### ACADEMY OF MEDICINE ANNOUNCES NEW SUITER LECTURESHIP

The New York Academy of Medicine has announced the establishment of a new annual lectureship in accordance with the provisions of the will of the late Dr. A. Walter Suiter. The lectures will be held under the auspices of the Committee on Public Health Relations of the Academy.

The first of the series will be delivered on Thursday, November 2, at 8:30 p.m., by Dr. Stuart Mudd, professor of bacteriology at the University of Pennsylvania. The subject of the lecture will be "Airborne Infection—The Rationale and Means of Disinfection of Air."

This lecture is open to the general public.

#### AMERICAN SOCIETY OF ANESTHETISTS TO MEET IN OCTOBER

The next meeting of the American Society of Anesthetists will be held at the New York Academy of Medicine, Room 550, October 12, at 8:00 p.m.

The business session at 8:00 p.m. will be followed by the scientific session at 8:15 p.m. The first lecture will be "Acute Pulmonary Edema During Sympathectomy," a case report by Dr. Morris Bien, of Mount Sinai Hospital. This will be followed by "Respiratory Physiology," a lecture by Dr. Carl F. Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine. These lectures will be discussed by Drs. Herbert Maier, New York, and J. Burns Amberson, New York.

#### HEALTH SERVICE CONDUCTS POSTGRADUATE COURSE IN VENEREAL DISEASE

The U.S. Public Health Service's eighth postgraduate course in venereal disease control will be conducted at the Public Health Service Medical Center, Hot Springs, Arkansas, October 19 to November 8. Dr. J. R. Heller, Jr., chief of the Venereal Disease Division of the Public Health Service, Federal Security Agency, announced on September 15. The course will be given to health officers and to private physicians cooperating with State and local health department venereal disease control programs. Lectures and demonstrations will be given by outstanding specialists.

Physicians who will conduct the course are Dr. Udo J. Wile, Ann Arbor, Michigan; Dr. Ruth Boring Thomas, New York City; Dr. Austin V. Deibert, Fort Douglas, Utah; Dr. Richard C. Arnold, Staten Island, New York; Dr. Eugene A. Gillis, New Orleans, Louisiana; and Dr. Robert B. Greenblatt, Hot Springs, Arkansas.

Applications for admittance to the course should be submitted promptly through State health officers, to the Medical Officer in Charge, U.S. Public Health Service Medical Center, Hot Springs National Park, Arkansas.

#### GASTROENTEROLOGIC CONFERENCES AT BELLEVUE

The gastroenterologic conferences at Bellevue Hospital which began Monday, October 2, will continue every Monday throughout the ensuing year.

The conferences are held at 3:00 p.m. in the G 6

amphitheater (F & G Building). As in previous years, these conferences consist mainly of a presentation of the clinical, pathologic, and radiologic findings of current abdominal cases that have come to operation or autopsy.

Chemists to the Medical Profession for 43 Years

THE ZEMMER COMPANY • Oakland Station • Pittsburgh 13, Pa.

Thiamine deficiency, with its protean manifestations, ranges in degree from minor nutritional affections to frank beriberi. Therapy requires a similar range of dosage, from the nutritional supplement of 1 mg. daily to the massive dosage of 100 mg. in delirium tremens or the dilated heart of wet beriberi. While the latter conditions are only rarely encountered, the physician will welcome the availability of adequate dosage forms, for parenteral as well as oral administration. Bethiamin, the Massengill brand of crystalline thiamine hydrochloride, provides practically every dosage form which may be required.

# BETHIAMIN

Physicians are invited to send for the new catalog of Massengill Pharmaceuticals Vitamins and Hormones For Parenteral Administration.

For oral administration, Bethiamin is available in capsules containing 1 mg.,  $3\frac{1}{2}$  mg., 10 mg., and 15 mg.; for parenteral administration, in 1 cc. ampuls containing 1 mg., 10 mg., 50 mg., 100 mg. and in 10, 30 or 60 cc. rubber-capped vials. In liquid form Bethiamin Elixir contains 6 mg. of thiamine hydrochloride per fluidounce.

# Bacillary dysentery — a new conquest for

## SULFADIAZINE *Lederle*

IN THE CONTROL of acute bacillary dysentery, SULFADIAZINE presents certain advantages over the other sulfonamides that have gained increasing recognition.

Prolonged high blood levels tend to prevent extension of the infection.

Secretions in the gut become bacteriostatic.

Bacterial growth within the intestinal mucosa tends to be inhibited.

Extensive clinical experiences in military and civilian practice supports the views and indicates increasing use of SULFADIAZINE in this field.

# *HEROES... Behind Masks*

BOMBS screaming down... shells crashing...  
 the crazy chatter of strafing planes' machine  
 guns... they're the "background music" of the  
 drama that's played on every fighting front every  
 day by the surgeons of the field clearing-stations.  
 "Soldiers in white"... heroes—behind masks.

Naturally we are proud that their choice of a  
 cigarette—in those moments when there's a brief  
 respite for a heartening smoke—is likely to be  
 Camel. The milder, rich, full flavored brand fa-  
 vored in the Armed Forces all over the world.

Camel is truly "the soldier's cigarette"!

TO MAINTAIN THE SUPPLY  
OF PENICILLIN HERE . . .

TO INCREASE THE SUPPLY  
OF PENICILLIN HERE . . .

## PENICILLIN *Schenley*

THE TASK of penicillin production cannot be considered complete until there is sufficient to meet not only the widest needs of military medicine, but those of civilian practice as well.

Toward this end, the Schenley research staff—with a background of long experience in the study of mold and fermentation processes—early devoted itself to the project of developing a large-scale method of penicillin production.

A procedure was established that led to our being designated one of the 21 firms to produce this valuable weapon of modern medical science.

Today—thanks to the tireless devotion of science and industry—this problem of mass production is being solved, and penicillin is fast becoming a standard pharmaceutical agent on all of the world's warring fronts. And, as the supply increases, it will become more and more familiar in civilian practice.

## Quick, Direct, Dual-Action

In the treatment of colds and sinusitis, this unique stable chemical compound assures rapid nasal decongestion and ample bacteriostasis.

And, in chemically combining Neo-Synephrine with the minimum desired amount of sulfathiazole, the vasoconstrictive power and the full bacteriostatic action of these two great therapeutic agents remain undiminished. The solution is notable for low toxicity, prolonged duration and is effective even on repeated administration.

# Neo-Synephrine Sulfathiazolate

*Available as a 0.6% solution in a buffered approximately isotonic vehicle in 1 oz. bottles with dropper for prescriptions, and in 16 oz. bottles for office and hospital use.*

# MEDICATION *by* INFILTRATION

For prolonged, effective decongestion and analgesia in local inflammatory conditions, Numotizine's mode of action is outstanding.

By infiltration through the emplastrum and through the epidermal and dermal layers, the guaiacol, beechwood creosote and methyl salicylate are slowly absorbed, and thereby produce both local and systemic therapeutic effects. Numotizine exerts its effectiveness gradually and steadily over a period of eight

**NUMOTIZINE**  
THE PRESCRIPTION CATAPLASM  
**NUMOTIZINE**

hours or more.

Numotizine is clean and simple to use—it replaces the inconvenient, older methods of applying "ex-heat"—thus eliminating need for constant attention.

Indicated in chest conditions, sprains, neuralgias, strains, epididymitis, superficial abscesses, myalgia, neuritis and similar conditions.

4-oz., 8-oz., 15-oz. and 30-oz. jars

# CAMP ANATOMICAL SUPPORTS

for

## NEPHROPTOSIS

TOGETHER with treatment for any existing infection of the urinary tract, Camp Supports have proven valuable adjuncts in the relief of symptoms in many cases.

Camp-trained fitters have been instructed to consult the physician as to the position required for the fitting, if reclining or partial Trendelenburg. In the event that the physician desires the use of a pad, the fitter has been instructed to obtain information as to the type of pad to be used and to ask the doctor to mark on the garment or blue pencil upon the patient the exact location of the pad.

### *Advantages of Camp Supports in Conditions of Nephroptosis:*

1. The "lifting" power of Camp Supports is from below upward and backward.
2. Camp Supports are an aid in improving the faulty posture that sometimes accompanies renal mobility.
3. Camp Supports are easily and quickly adjusted.
4. Camp Supports stay down on the body by reason of the foundation laid about the pelvis.
5. Camp Supports are comfortable.
6. Camp Supports are economically priced.

*Camp fitters ask patients to return to their physicians for approval of the fitting.*

# the local problem in

## ACNE VULGARIS

The local problem in acne vulgaris is to remove the excessive sebum with the least amount of irritation. This cannot be accomplished with ordinary soap and water as easily as with sulfated oils. Swartz and Blank report gratifying results when Acidolate, the modern sulfated-oil detergent, is utilized in place of soap to secure and maintain skin cleanliness (*J.A.M.A.* 125 p. 3031, May 6, 1944).

Acidolate, founded on scientific research and backed by extensive clinical experience, offers the following advantages:

1. It is a logical and competent solvent of sebum.
2. It contains only those fatty acids that are non-irritating to the skin.
3. Its pH of 6.5 is compatible with that of the skin.
4. It is non-abrasive, water-miscible and free of perfume and pigment.

## Highly Potent—

A review of the many published papers on the employment of "Premarin" in clinical practice provides ample evidence of the value of this highly potent natural estrogen at the menopause. A correlation of the data indicates that as little as one tablet daily provides effective treatment for the average case; even severe cases show prompt response to "Premarin" therapy. Although it is highly potent, "Premarin" is exceptionally well tolerated, and unpleasant side effects are rarely noted. In "Premarin" the physician will find the desirable characteristics of both the milder natural estrogens and the potent synthetic substances . . . without any of the disadvantages.

**Hypoallergenic Soy Bean Food  
A Borden Prescription Product**

MULL-SOY is a liquid emulsified food, prepared from water, soy bean flour, soy bean oil, dextrose, sucrose, calcium phosphate, calcium carbonate, salt, and soy bean lecithin; homogenized and sterilized. No vitamins are added, as they may be specifically allergenic.

# It's All in the Bottle

In preparing liver concentrates for use as hematinics, all too often refining defeats its own purpose. Too much refining removes valuable hemoglobin-building fractions which are then discarded—down the drain.

## HEPATINIC 'MCNEIL'

—when employed in the management of secondary anemias—gives assurance that the *full* therapeutic value of liver concentrate is present. The liver concentrate incorporated in palatable Elixir Hepatinic is in a crude, unfractionated form, thereby supplying certain hemoglobin-building substrates not available where liver is concentrated by excessive refining.

*You will be pleased with this significant feature of  
Elixir Hepatinic.*

Each fluidounce contains: Ferrous Sulfate 12 gr., Crude Liver Concentrate (equivalent to 660 gr. fresh liver) 60 gr., Thiamine Hydrochloride 2 mg., Riboflavin 4 mg., Niacinamide 20 mg., together with Pyridoxine, Pantothenic acid, Choline and other factors of the vitamin B complex.

*Elixir Hepatinic is supplied in bottles of  
one pint and one gallon*

# RICCI

## Genealogy of Gynaecology

By JAMES V. RICCI, B.A., M.D.

Clinical Professor of Gynaecology and Obstetrics, New York Medical College; Director of Gynaecology of the City Hospital, New York; Attending Gynaecologist and Obstetrician, Flower and Fifth Avenue Hospitals; Consultant in Gynaecology and Obstetrics, Downtown Hospital, New York, etc.

This remarkable book presents the Romance of Gynaecology. The author, with an amazing devotion to his specialty, has unearthed from seemingly endless sources an immense amount of material dealing with the theories and therapies of female ailments. The book unfolds in orderly fashion the development of Gynaecology as practiced for a period of approximately four thousand years.

"One can be free with praise of this full, well-documented narrative, modestly told, clearly representing years of patient labor. . . . One might add that volumes such as this, directed at the reader who is not a professional historian himself, possess certain advantages when not composed by the professional historian; and there are practically no medical histories in English, general or special, by professional medical historians, anyhow. . . . We know of no other history of this subject in English that compares with this work in its fulness, yet readability, its richness of illustrations, its documentation and its guides to further reading. For the clinician and layman aware of medico-historical values, this narrative is highly recommended; for all, it is a valuable reference work that leads to a rich list of sources."

## Now "what the doctor orders"

**D**ISCOVERIES in biochemistry and nutrition have helped the bakers of America to provide a modern loaf of bread that is better for balancing wartime diets

The most inexpensive and plentiful of foods, bread now has even more reason for being the mainstay of the national diet.

Bread is one of the most economical sources of food-energy. That is a fact long recognized by your profession.

Bread has important protein content. That means it is indicated as a com-

plement of protein foods now available in lesser quantities.

And now bread is a protective food as well. Every loaf of bread sold today must be enriched with vitamin and mineral factors — thiamin, riboflavin, niacin and iron in prescribed and valuable amounts.

Because it now contributes all of these nutritional elements, bread has reassumed its traditional position as a basic food. Bread is now "what the doctor orders" for the modern diet.

## Bread *is* basic

*This is one of a series of messages run in the interest of the Bakers of America by the makers of Fleischmann's Yeast.*

No food (except breast milk) is more highly regarded than Similac for feeding the very young, small twins, prematures, or infants who have suffered a digestive upset. Similac is satisfactory in these special cases simply because it *resembles breast milk so closely*, and normal babies thrive on it for the same reason. This similarity to breast milk is definitely desirable — *from birth until weaning.*

A powdered modified milk product especially prepared for infant feeding, made from tuberculin tested cow's milk (casein modified) from which part of the butterfat is removed and to which has been added lactose, olive oil, coconut oil, corn oil, and fish liver oil concentrate.

One level tablespoon of Similac powder added to *two* ounces of water makes *two* fluid ounces of Similac. This is the normal mixture and the caloric value is approximately 20 calories per fluid ounce.

SYRACUSE, NEW YORK

# RELIEVE PAIN *without* GASTRIC IRRITATION

Gastric irritation is a common result of the hydrolysis of aspirin in the stomach. From the very first moment irritant salicylic and acetic acids are liberated. They often produce hyperacid symptoms.

*PRO-DOL offers effective aspirin therapy buffered and insulated against the deleterious side-effects of plain aspirin, without the disadvantages of alkalis.*

Each full dose incorporates 5 grains of acetylsalicylic acid with  $7\frac{1}{2}$  grains of dried aluminum hydroxide gel. Irritant acids of hydrolysis are neutralized and adsorbed as soon as they are formed. An exclusive PRO-DOL feature insulates acetylsalicylic acid from gel inside each tablet until used.

Use of PRO-DOL entails neither interference with peptic digestion nor compensatory rise in gastric acidity. No systemic alkalosis follows — this is due to PRO-DOL's buffer-point and to a non-toxic, non-absorbable gel.

*PRO-DOL is not advertised  
to the laity.*

## Chemical Combination Enables SAFE AND SIMPLIFIED THERAPY in Urinary Infections

Mandelamine, by combining in a single medication the recognized effectiveness of mandelic acid as an acidifying agent and the efficiency of methenamine as a bactericidal agent, offers the physician a safe and simplified method of treatment for urinary infections.

Gastro-intestinal disturbances, so common with other urinary antiseptics, are virtually eliminated when Mandelamine is used. It is especially valuable in the treatment of pyelitis of pregnancy, where its easy toleration does much to avoid aggravation of the nausea and vomiting often associated with the gestatory period. Other conditions for which Mandelamine is indicated are pyelonephritis, cystitis, prostatitis, and the infection accompanying renal calculi.

In addition, the course of administration with Mandelamine is relatively simple inasmuch as accessory acidification of the urine, constant checking of the urinary pH, and the restriction of diet and fluid intake are generally unnecessary.

We suggest that you try Mandelamine in your practice so that you may observe its many advantages both to you, and to the patient.

Supplied in enteric coated tablets of 0.25 Gm. each, sanitized, in packages of 120, 500 and 1000.

## R. B. C. PRODUCTION LINE

In iron deficiency anemias, 'Tabloid' 'Ferad' No. 2 constitutes a classic specific for the restoration of uniform, normal erythrocytes. A high degree of hematopoiesis is achieved with a minimum of gastric irritation, constipation and diarrhea.

'Tabloid' 'Ferad' No. 2 contains ferrous sulfate, the most effective form of iron for the treatment of iron deficiency anemias. The inclusion of a small amount of anhydrous sodium carbonate tends to neutralize the acidic properties of ferrous sulfate and thus improve tolerance.

## *Editorial*

### Edward Charles Podvin, M.D.

Dr. Edward Charles Podvin, Assistant Secretary of the Medical Society of the State of New York since 1936, died at his home at 2564 Marion Avenue, the Bronx, September 27, 1944. He was 68 years old.

Dr. Podvin, who had practiced medicine in the Bronx since 1903, was a native of Hudson Falls, New York, and was a graduate of Manhattan College and Albany Medical College. He was chairman of the Bronx Tuberculosis and Health Committee, former President of the Catholic Physicians'

Guild of the Bronx, and consulting gastroenterologist at Fordham Hospital.

His tall bearded figure, heavy gold watch chain, spectacles, and genial smile were familiar to the physicians of the State at annual meetings as he stood on the rostrum at his appointed task of calling the roll of delegates and presiding during the brief absences of the Secretary.

His presence will be missed at both the annual meetings and the sessions of the Council. *Ave atque vale.*

### Plain Talk; III

There is one good point about being in agreement about something—you can go about your business expeditiously without wasting a lot of time squabbling.

Take voluntary prepaid medical care, for instance. There used to be some doubt and uncertainty about it; would it work? Did the doctors think it a good thing? How did the people feel about it? Would

the medical profession support it? That was long ago.

Now the medical profession is squarely behind it, the public wants it, nobody opposes it who is sufficiently informed on the subject to know what it is all about. Take one aspect of it, for example. How can any plan to insure people against illness work unless the doctors are behind it? The whole

principle of insurance depends upon *enough* lives, or houses, or automobiles of just plain people who pay premiums to meet the *cost* of the thing they *insure against*; in this case, *illness*. Next there must be enough doctors to treat the people, good doctors, too, or the people won't buy the insurance. Why should they put up with other than the *best* medical care? When they buy something they want the best that can be had. That is why the doctors themselves, through their Medical Society of the State of New York, are sponsoring voluntary prepaid medical expense indemnity insurance. That is why the Medical Society is setting up, right now, a Bureau of Medical Care Insurance with a full-time director so that the people can have the kind of insurance they want, backed by the doctors themselves. Such insurance is *safe* insurance.

Many of you remember the watch that made the dollar famous. It was good because it had responsible people and good workmanship and materials in it. Voluntary medical care insurance backed by responsible doctors is good for the same reason. Such insurance provides medical care of a

quality that the doctors, through their State Medical Society, propose to furnish to those who want to buy insurance against illness.

It is not to be anticipated that you can start with a perfected plan. You can start with an actuarially *sound* plan, and you can set your upper limits of acceptance in a manner or at a level to include 94 per cent or thereabouts of all the people in the country. Then, after you have enough subscribers to your plan you can modify the details as may be necessary, and as accumulating *experience* seems to direct. But you certainly cannot go until you start.

Even though the people want prepaid medical care insurance it will take some time to cover 94 per cent, say, of the people of the country, or even of this State. Policies have to be written and marketed. So it's up to us to take the driver's seat and deliver the goods, isn't it? What is to stop us? Nothing that we can think of at the moment. Doctors have never yet been stopped from doing anything which they thought was for the public interest, and for the betterment of the public health, come hell or high water.

## Remarks of the President

In his addresses to the various District Branches of the Society, President Baucus covered many of the activities of the organization in its relation to the public and to the profession. For the benefit of those who could not attend the meetings we reproduce here, in part, the greater portion of his remarks, supplementing those which were published with editorial comment in previous issues of the JOURNAL.

"The Medical Society of the State of New York has one of the most comprehensive and best-conducted postgraduate teaching programs in this country. It is available to the entire profession as a series of continuous courses, and keeps our practitioners in touch with the newest worth-while developments in medical care. In these efforts we have the invaluable aid and wholehearted support of the New York State Department of Health. It is really a joint teaching program for the eventual good of the people of this State. A major portion of the activity of the American Medical Association is devoted to the education of the profession. We should loyally support this our parent organization,

appreciating its part in sustaining modern medical practice. Hopefully we look forward to the time when the public becomes fully cognizant of the truth, namely, that the greatest resources of organized medicine are used in the promotion of public well-being.

"Our function in the American scene is, first and last, to prevent illness, cure disease, comfort, and prolong life. This is our profession. We should like to think of it alone. But there are constantly those who would lower medical standards for their own selfish purposes. There are those who would ever change our well-planned order of advance to fit it into economic schemes born of an impractical philosophy. Experience costs time and it is worth at least that much.

"Primitive medicine sometimes demanded of the physician that he not only heal the sick but that he cast a spell upon the patient's enemies. Modern medical care recognizes the outside hazards to man's comfort and health, too—the doctor thinks of the many needs and desires of the human and his family, and in general studies and appraises the conditions which may make for departure from good health. He not only wants to cure the disease, but he wants to know how it came about, and thus perhaps how it may be prevented. In this respect

thinking is objective to the common welfare, but when we think of the patient, sick or apparently ill, we think of him and we care for him as an individual. His mind is personal and so is his body. Can an individual be created, born an individual, dies an individual, goes to his Maker an individual. Can any system of medical care ignore this principle, old as the creation? A true analysis of the patient's thoughts, symptoms, and signs defies any robot system of investigation. The sick person is in trouble, he wants the physician acting for his benefit to be ever so specially interested in him—so to speak, in his corner. The patient is the employer, respected and free. Modern economics should make it possible for the poorest sick man to be the employer of the physician. That is not an unsolved problem of society—it can be solved simply and effectively to the greatest good and with the complement of the best-paying investment on this earth.

"Under the care of our present system of modern medicine the average age of life in the United States has increased to the greatest known for all time. In 1880 the average length of life was 36. In 1920 it was 53. From 1920 to 1944 it progressively increased to the present age of 62. The figures of 1920 to 1944 are especially interesting. Have the

economists of the country done as well with the financial condition of the patient during that period? The answer is obvious."

Medicine is constantly under fire for its alleged shortcomings. Admittedly there is room for improvement. A point which lay critics overlook in their zeal is that nobody is more critical of medicine than the physicians themselves. It is this fact which has advanced scientific medicine so fast that the political and economic structure of the country seems still to be riding around in a horse and buggy trying to keep up.

Medicine will continue its efforts to improve the public health and to prolong the life of man so that he will be able, with better health and more years to live, to criticize medicine and its works over a longer period of time, and will be freer from the ills which now divert attention, and which, we hope, he will in the future devote to better and more constructive criticism of medicine.

## Postwar Training for Medical Officers

Under the title "Continuous Medical Education"<sup>1</sup> we referred previously to the problem of the provision for continuous medical training. We set forth in detail the views of Selective Service and the War Relocation Authority on the question of the premedical and the medical student.

In the issue of August 1, 1944, under the title "Continuous Medical Education, II,"<sup>2</sup> we referred again to the subject about which nothing has yet been done except that the Miller bill (*H.R. 5128*), modifying and amending Section 5 of the Selective Training and Service Act of 1940, is under consideration.

If grave concern exists as to the continuous flow of premedical and medical students, the problem of postwar training for medical officers, though not so immediately pressing, is no less weighty.

The Council on Medical Education and Hospitals of the A.M.A. has taken cognizance of this need of postwar training for medical officers, and in the August 19 issue of

the *J.A.M.A.* published a study of the future educational objectives of medical officers based on questionnaires sent to officers in the armed services.

Editorial comment of interest to all physicians appeared in the *J.A.M.A.* for September 23, 1944, and which we reproduce in part:

"Probably 10,000 medical officers will want house-officer training of six months or more. Since demobilization will probably extend over some time, the number of additional places required will probably approximate 5,000 during the first year. Apparently most expansion will be required in otolaryngology, surgery, obstetrics and gynecology, and ophthalmology, which may need to double their facilities. Expansions of 50 to 70 per cent seem to be indicated in urology, internal medicine, orthopaedic surgery, and pediatrics.

"Somewhat fewer officers are likely to seek shorter courses; about 9,000 officers will seek full-time training of one to six months' duration. In 1943-1944 there were nearly 27,000 physicians enrolled in such courses. However, over 90 per cent of these were in short courses of about a month. Apparently more than 90 per cent of those desiring review or refresher courses will seek training in somewhat longer courses of two to six months' duration. Many more courses of that duration will be required.

"In the light of the figures given, all institutions

<sup>1</sup> New York State J. Med., Vol. 44, No. 14, July 15, 1944, p. 1537.

<sup>2</sup> New York State J. Med., Vol. 44, No. 15, Aug. 1, 1944, p. 1647.

which can contribute to meeting the need are obligated to review their resources and prepare estimates of the additional facilities they can provide, to facilitate the achievement of the program outlined (page 257).

"The communication from Col. Perrin H. Long, published on page 239 of this issue, further underscores the deep concern of medical officers with regard to their further training after the war and indicates that the work being carried out by the Committee on Postwar Medical Service meets a real demand. The suggestions of Colonel Long are similar to the program already being developed. With continuing cooperation of the Committee on Postwar Medical Service, the Council on Medical Education and Hospitals, the Surgeons General of the armed forces, medical schools, American boards in the medical specialties, and others primarily concerned, there is every reason to expect that the needs will be met. Information

now being collected from all educational institutions will be made available in the near future. In the meantime, medical officers can be assured that every effort is being made, and with success, 'to cut through to the goal, because then, with the facts before them . . . (medical officers) . . . will be able to plan their existence in the postwar world.'"

It is interesting to note the apparent tendency of the medical officers to choose the longer periods of training. It is to be hoped that such county societies and other associations which have been foresighted enough to provide them will make available such funds as may be necessary to assist in this program through loans for this purpose. Undoubtedly they will be needed.

## Sulfonamide Renal Pathology

As the limitations and indications of sulfa therapy become more clearly defined, a distinct trend is discernible toward the extension of its usage. This trend is most evident in the realm of prophylaxis against infections which are inherently serious or which are likely to assume an epidemic character.<sup>1,2,3</sup> This relatively new extension of sulfa therapy gives great promise of materially reducing the incidence of diseases in which the causative factor is amenable to such therapy. At the same time this mass chemoprophylaxis entails certain perils which are worthy of repeated emphasis despite an ample literature which warns of the toxic reactions of sulfa drugs.

It is fully recognized that the kidney may suffer injury from sulfa compounds. Such renal pathology may assume a mechanical nature because of masses of crystals accumulating in the renal parenchyma, pelvis, or the ureters, sometimes to the point of obstruction. It is not so well known, however, that these same drugs, particularly sulfadiazine, may produce toxic intrarenal lesions which are quite distinct from the mechanical damage caused by aggregations of crystals.<sup>4</sup> These toxic lesions may assume the form of tubular degeneration or necrosis, and

glomerular changes. To further complicate the picture, toxic renal damage may be associated with obstruction. While the latter is the more common disturbance, it is less serious because the obstructive masses may be removable. Toxic renal effects, however, once initiated, are more ominous and require prompt recognition, for the only effective measure is the immediate cessation of administration of the drug.

The appearance of sulfa crystals in the urine calls for the administration of alkali until the urine is strongly alkaline. A superior procedure is the routine administration of sufficient alkali with the sulfa compound to render the urine definitely alkaline. If hematuria ensues, especially if there is no crystalluria, toxic renal changes should be suspected and the drug discontinued. By observing such precautions and avoiding toxic effects, a promising and effective therapeutic field can be safely developed, devoid of the drawbacks inherently associated with this procedure.

# EXPERIENCES WITH THE USE OF DESICCATED THYROID

## Methods of Detecting Self-Induced Hyperthyroidism, with a Report of a Case in Which Auricular Fibrillation Occurred

LEWIS M. HURXTHAL, M D, Boston, Massachusetts

SINCE the subject of "Practical Management of Endocrine Disorders," as listed on the program, is too wide in scope to be discussed in the allotted time, I shall limit my remarks to certain thyroid problems which rarely receive attention and are of clinical significance. These problems are concerned with the use of desiccated thyroid. First, I shall discuss the use of thyroid in myxedema associated with angina pectoris, second, other complications arising from its use, and, last, thyroid addiction and its detection.

### Myxedema Complicated by Angina Pectoris

The treatment of myxedema usually is a simple procedure, but complicated situations, which may lead to fatalities, arise often enough to warrant calling attention to the dangers of treatment with routine doses of thyroid.

Several authors have stressed the importance of caution in treating patients with myxedema and angina pectoris. Christian<sup>1</sup> was one of the first to point this out. In 1939, Bartels<sup>2</sup> reviewed the cases of spontaneous myxedema treated at the Lahey Clinic, and showed that 15 of 59 patients with spontaneous myxedema either had angina of effort before treatment or developed angina or coronary infarction during treatment. In these cases, doses of desiccated thyroid did not exceed 2 grains daily.

The evidence that atherosclerosis is more frequent in long-standing myxedema is fairly convincing. The relationship between hypercholesterolemia and atherosclerosis is interesting. The causal relationship between the two will, I believe, eventually be established, although to date, in spite of animal experimentation, positive proof probably does not exist. I have seen several patients from families in which many, including young adults, were afflicted with angina of effort or coronary infarction and associated hypercholesterolemia, thus giving further support to the theory of relationship between hypercholesterolemia and coronary atherosclerosis.

Heart pain in myxedema may occur at different times and under different circumstances. It may begin with the onset of myxedema and be relieved as treatment of myxedema progresses. On

the other hand, anginal pain may increase on the routine treatment of myxedema consisting of 1 to 2 grains of thyroid daily. When this occurs, smaller doses of  $\frac{1}{10}$  to 1 grain a day may be tolerated. Some patients may have anginal pain on small doses, while others may have it only when larger or maintenance doses are given.

Anginal pain is not commonly present before treatment, but is more likely to occur with treatment. Coronary infarction or prolonged anginal seizures may occur at the onset of treatment, when the dose is increased, or when the patient appears to be well stabilized. Thus, coronary symptoms may appear at any time, and it is sometimes impossible to predict which patient will obtain relief of symptoms and which patient will appear to have an aggravation of symptoms.

In general, the younger the patient and the shorter the duration of the disorder the less chance there is of the development of angina pectoris. A young patient with anginal symptoms before treatment is likely to obtain relief. The presence of hypertension, abnormal electrocardiographic changes, or obvious arteriosclerosis is of little help in predicting the course of events, consequently, treatment should be instituted with caution. Since there is no need of haste, small doses should be given during the first month or so of treatment.

One-fourth grain of thyroid (USP) should be the maximum initial dose. This may appear to be much too conservative, but, as I have said before, there is no advantage in haste. After several weeks the dose may be increased to  $\frac{1}{2}$  grain and so on up to  $1\frac{1}{2}$  to 2 grains a day, which is usually sufficient for complete substitutional treatment. If all signs and symptoms do not disappear in several months, larger doses will not, as a rule, improve the patient's condition.

If anginal symptoms appear at any stage of treatment, the amount of thyroid should be reduced and maintained at that level for one to two months. Then small increases of from  $\frac{1}{8}$  to  $\frac{1}{4}$  grain a day can be attempted. Some patients can detect an increase of  $\frac{1}{10}$  grain of desiccated thyroid a day because of anginal pain. This can be proved by placebo therapy. At the Lahey Clinic we have tried various forms of thyroid without success, particularly those products which are claimed to cause less heart stimulation than ordinary desiccated thyroid. Thus, patients who

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944.

From the Department of Internal Medicine, the Lahey Clinic, Boston.

FIG. 1. Chart showing observations on excretion of total urinary iodine during nine weeks following cessation of self-administered desiccated thyroid (U.S.P.), estimated to have been 8 to 12 grains. The persistent high pulse rate was due to auricular fibrillation at the onset; later auricular flutter after digitalization; then return to normal rhythm. The initial drop in weight may have been due to fluid retention because of excessive heart rate.

develop anginal pain on thyroid therapy may be good subjects for comparison of various thyroid products.

As a rule, an increase in anginal symptoms means that the substernal pain or discomfort occurs more easily with emotion or exertion. On the other hand, in some patients it may indicate merely a more acute perception of pain or it may be related to quickened motor or emotional activity from a lessening of the myxedema itself. It would appear, however, that the pain is a manifestation of a greater load on the heart in supplying the demands of increased metabolic activity, not only peripherally but in the heart itself.

Myxedematous changes occur in the heart, and it is reasonable to assume that there is a relative coronary insufficiency which decreases as the myxedema decreases unless actual thrombotic

lesions have occurred. If such exist, the heart may be unable to meet normal metabolic demands without resulting pain. In some patients who are receiving thyroid, prolonged anginal attacks may occur at rest, without definite changes of coronary infarct either electrocardiographically or otherwise. A lowering of the height of the T waves may occur following such attacks, but since thyroid usually is omitted temporarily in these cases the change in T waves may result from this withdrawal. There is little doubt as to actual infarction in other patients with myxedema.

Some years ago I heard of a patient who could tolerate no thyroid by mouth and was given thyroxin intravenously by an enthusiastic physician. Death occurred in an acute anginal attack within twelve hours. This patient probably did not have a coronary infarction but rather an acute anoxemia of the heart resulting in death.

Needless to say, all thyroid should be discontinued for several weeks following prolonged anginal seizures or coronary infarction, then given again in minimum doses, and increased to optimum tolerance (Table 1).

Other Complications

In the treatment of myxedema the physician should bear in mind the possibility that it might be secondary to pituitary tumor with panhypopi-

TABLE 1.—TOLERANCE TO DESICCATED THYROID IN MYXEDEMA AND ANGINA PECTORIS

A. No pain before treatment	
1.	Tolerance 1-2 grains (usual)
2.	Tolerance 1/10-1/4 grain only (unusual)
3.	Tolerance 1-2 grains after initial doses of 1/10-1/4 (unusual but possible)
4.	Unable to tolerate thyroid (rare)
B. Pain before treatment	
1.	Relief with 1-2 grains (avoid but may occur)
2.	Relief with 1-2 grains after initial doses of 1/10-1/4 (advised and often possible)
3.	Increased pain with 1/10-1/4 grain (not unusual)
4.	Increased pain with 1-2 grains (usual but avoid)

FIG. 2. Electrocardiogram showing auricular flutter, which followed digitalization when auricular fibrillation was present. Normal rhythm on right.

tuitarism. Myxedema following thyroid surgery is naturally a primary myxedema, as is also the myxedema from thyroiditis, in which a hard diffuse enlargement of the thyroid gland is present. While there are many clinical differences between panhypopituitarism and primary thyroid myxedema, there are rare cases of hypopituitarism in which all the clinical signs of primary myxedema occur.

Myxedema in these cases is, therefore, the most outstanding disturbance in hypopituitarism, but other glandular deficiency may lurk in the background, particularly pituitary hypoadrenalism. In these cases desiccated thyroid may be poorly tolerated, precipitating an acute adrenal insufficiency. Thus routine roentgenologic examination of the skull in patients with what appears to be spontaneous myxedema is indicated especially in those who have not been operated upon for goiter or have a goiter, and particularly in those who have hypotension and complete suppression of menses.

The use of desiccated thyroid when not specifically indicated has other dangers. Ordinary doses are not likely to have a serious effect on the heart of a person without myxedema unless,

of course, coronary insufficiency is present. With large doses, latent diabetes may become clinically significant. In 1931, I<sup>2</sup> reported our observations of patients who developed exophthalmic goiter following the use of desiccated thyroid for weight reduction. To be sure, this must be a relatively rare occurrence, considering the large number of people who take thyroid. From my experience with patients for whom thyroid has been prescribed, I would estimate conservatively that there are many more people without thyroid deficiency taking thyroid than there are people taking thyroid for myxedema.

### Thyroid Addiction or Self-Induced Hyperthyroidism

For some people large doses of thyroid are a source of energy and perhaps mental stimulation

TABLE 2.—CHOLESTEROL VALUES

Date	Basal Metabolic Rate Percentage	Pulse	Cholesterol Mg. per 100 cc.
March 15, 1938	+80	100	112
October 22, 1938	+49	84	175
May 3, 1939	+10	80	274

FIG. 3. Roentgenogram of heart during auricular fibrillation (left) and during normal rhythm (right).

FIG. 4. Chart showing rapid fall in pulse and basal metabolic rate on two occasions while patient was in hospital.

Fig 5 Chart showing urinary iodine excretion while patient was in hospital. Note rise after injections of thyroxine and ingestion of desiccated thyroid. The increase in urinary iodine after injection of pituitrin is being investigated.

or intoxication. Others use large doses of thyroid in an attempt at weight control. In fact, some people indulge in this method of stimulation secretly, yet consult a physician for the resulting symptoms. Some even submit to a subtotal thyroidectomy for symptoms which they have induced secretly by self-administered thyroid. The new drug laws should prevent this, but there are illegal ways of obtaining thyroid, just as there are ways of obtaining morphine.

What are the reasons for suspecting the secret self-administration of thyroid, or, one might better say, thyroid addiction? This possibility should be suspected in patients who have clinical evidence of hyperthyroidism, in whom a typical history of thyrotoxicosis can be elicited, but who, on examination, have a thyroid gland of normal size and consistency. Palpation of the thyroid

gland is a great help in diagnosis. Less than 2 per cent of patients with exophthalmic goiter have a gland which on palpation can be considered normal. Thyroid addiction should also be suspected in patients who have had a subtotal thyroidectomy and who continue to be thyrotoxic without palpable recurrent or persistent hyperplastic remnants.

My first experience with this type of case occurred some fifteen years ago when a patient who later became psychotic, who had been operated upon for hyperthyroidism without benefit and subsequently died of heart failure, was reported by social workers to have concealed in her room many empty bottles labeled desiccated thyroid. No further proof of self-administration was obtained, but this incident served as a reminder of this possibility.

FIG. 6. Chart showing observations when thyroid was discontinued.

The most recent case observed was of special interest because of the cardiac findings. The patient had continued to lose weight since a radical subtotal thyroidectomy was performed by a reputable surgeon eight months before. She had also developed auricular fibrillation. When questioned as to the possibility of taking thyroid, she denied it. No thyroid remnants were palpated, and the basal metabolic rate was +45 per cent. The pulse rate was 140 and totally irregular. The skin was warm, moist, and flushed. Tremor, stare, and slight exophthalmos were also present.

The proof of self-induced hyperthyroidism was demonstrated as follows: On analysis of a forty-eight hour urine specimen, a quantity of iodine was found which exceeded by five times the amount which is found in severe exophthalmic goiter. On this basis, her daily intake was estimated at 8 to 10 grains or more a day. The total blood iodine was 12 micrograms per cent, which was slightly elevated but not helpful in diagnosis. When confronted with the statement that thyroid had been recovered from the urine and that proof of purchase existed, a confession was obtained. When the patient was questioned concerning the reason for taking thyroid and the amount, the reply was "a small handful daily to provide pep." Since stopping thyroid, the heart has decreased in size, its rhythm is regular, the pulse

rate is normal, and the weight has increased. To date no clinical evidence of myxedema has occurred (Figs. 1, 2, and 3). Needless to say, such persons must be rather unstable, although after the effects of thyroid wear off they hardly can be called truly psychopathic.

If iodine studies are impossible, a one to two weeks' hospital stay usually will bring about a normal metabolic rate and disappearance of hyperthyroid symptoms. With discontinuation of the thyroid, the basal metabolic rate drops rapidly. I was deceived by the rapid drop of the basal metabolic rate in one patient. On one occasion it dropped from +85 to +8 per cent in nine days, and on another occasion from +65 to +6 per cent in twelve days. Not until urinary iodine studies were made did I realize that this was possible. With the drop in metabolic rate, there was also a drop in pulse rate and a disappearance of hyperthyroid symptoms and signs (Figs. 4 and 5). The cholesterol was 112 mg. per 100 cc. of blood with a metabolic rate of +90 per cent, and 175 mg. with a rate of +49, whereas when the rate was +10 the cholesterol was 271 mg. (Table 2).

From these observations it appears that either the basal metabolic rate drops quickly after discontinuance of large doses of thyroid or a true basal metabolic rate is not obtained when the pa-

tient is under the influence of thyroid. This discrepancy occasionally occurs in patients with extremely toxic thyroid glands whose first metabolic test may exceed +100 per cent but on subsequent days may be +60 to +70 and remain at that level.

Another patient continued to take thyroid tablets while in the hospital, having had a bottle of them smuggled into her room in a candy box. This patient ran a high metabolic rate and lost weight under observation on 4,000 calories daily. A glucose tolerance test showed a diabetic type of curve. Although the thyroid gland was normal to palpation, a subtotal thyroidectomy was performed and a normal gland was found.<sup>4</sup> Two months later the metabolic rate was still elevated and all symptoms persisted. Later, on readmission to the hospital, a search of the patient's room revealed thyroid tablets in a handbag. The basal metabolic rate returned to normal and the symptoms disappeared. Urinary iodine studies gave results similar to those in the other cases (Fig. 6). Some months later she developed myxedema, which now has been controlled for four to five years with  $\frac{1}{2}$  grain of thyroid daily.

Another patient who took large doses of desiccated thyroid had a basal metabolic rate of 100 per cent. The total blood iodine was 42.7 micrograms per cent, and the urinary output of iodine was 2,436 micrograms in twenty-four hours. It is well to point out that with a large output of urinary iodine one must be careful to inquire if an iodine preparation, such as Lugol's solution, has been taken. A patient with exophthalmic goiter on iodine in the usual doses of 10 to 30 drops a day has a total blood iodine of 50 to 75 micrograms

per cent, and a twenty-four hour urine output of 35,000 to 90,000 micrograms.

Even with adequate proof of thyroid ingestion, not all will confess. One patient repeatedly observed in the hospital never did admit taking the tablets, since she apparently did not take them to the hospital with her (Figs. 4 and 5). Several others who were not observed in the hospital also would not admit thyroid addiction even though blood and urinary iodine studies for a period of twenty-four hours were pretty conclusive. Some patients apparently take thyroid in large doses so that they can eat as they please without weight gain. In others the motive of desiring to attract attention or sympathy seems a possible cause.

Many nervous persons with anxiety states or neurocirculatory asthenia may have a high metabolic rate, and with rest in bed the metabolic rate may come down. Because of this possibility, a patient should not be accused of self-administration of thyroid unless the clinical picture is one of hyperthyroidism. With the exception of exophthalmos and an abnormal gland, induced hyperthyroidism is indistinguishable from the real hyperthyroidism, and considerable detective work sometimes is necessary to establish thyroid addiction.

### NATIONAL CONFERENCE ON VENEREAL DISEASE CONTROL IN NOVEMBER

A national conference on postwar venereal disease control will be held in St. Louis, Missouri, November 9-11, under the auspices of the U.S. Public Health Service, it was announced on September 7 by Surgeon General Thomas Parran, and Dr. J. R. Heller, Jr., Chief of the Venereal Disease Division of the Public Health Service, Federal Security Agency.

"The war has brought large increases in venereal disease infections in many parts of the world," said Dr. Heller. "Simultaneously, however, science has produced new drugs, and medical research has produced new methods to combat syphilis and gonorrhea.

conference," said  
ding experts in  
who will deter-

mine the best methods for giving wide application to recent advances in treatment of venereal diseases. Scientific papers will be presented by outstanding workers in the newer treatment methods. The U.S. Public Health Service, the National Research Council, and medical departments of the Army and

the Navy will report their findings on the effectiveness of penicillin in syphilis and gonorrhea, and

tensive treatment  
ks with arsenicals

dissemination of information to the public, and the development of new methods of control. Private physicians and hospitals will also make recommendations regarding their participation in the program."

Dr. Heller will outline to the conference specific questions which have grown out of developments in venereal disease control during recent years, specific answers to which, it is planned, will be formulated at the conference sessions.—*Release from the Office of War Information*

# SOME COMPLICATIONS OF CATARACT EXTRACTION

JOHN H. DUNNINGTON, M.D., New York City

THE removal of the crystalline lens has been discussed for many, many years. Every phase of the subject has been thoroughly reviewed time and again, yet to ophthalmologists it is still the most intriguing of all operations. Our interest in it does not wane, we talk about it on every occasion, we champion modifications in technic, we point with pride to our successful results, and we are equally chagrined at our failures. To my mind, this continued study of the problem is but evidence that the millenium, perfect cataract operation, is not at hand, for we still have complications to vex our minds and try our souls. It is of these vexations and tribulations that I speak.

The complications of cataract extraction may be divided into early and late manifestations. By early is meant those occurring either at the time of operation or during convalescence, while the term "late" is reserved for those not manifesting themselves until a considerable length of time has elapsed. This discussion will deal with some of the early mishaps because proper management of them does much to reduce the incidence of the late complications. Since time will not permit a complete coverage of the whole subject, I have selected three complications which I consider to be of greatest importance—viz: (1) hemorrhage into the anterior chamber, (2) iris prolapse, and (3) delayed restoration of the anterior chamber.

## Hemorrhage Into the Anterior Chamber

This complication has been the subject of intensive study by Wheeler,<sup>1</sup> Vail,<sup>2</sup> DeVoe,<sup>3</sup> and many others.<sup>4-10</sup> The literature is filled with statistics on its incidence and relationship to general disease, as well as on the merits of various prophylactic and therapeutic measures. Without going into a detailed discussion on all these points it is well to review some of them. Some ophthalmologists feel that this is a rare complication, while others see it with surprising frequency. The statistics on the incidence of its occurrence vary from 1 per cent to 35 per cent. DeVoe, in a careful analysis of 453 consecutive cases, found some postoperative bleeding to be present in 20 per cent. I agree with the statement of Vail, quoted by DeVoe, that "in a small series of cases carefully observed and recorded the frequency of

hemorrhage is apt to be greater than in a larger series less carefully watched."<sup>3</sup> The role of vascular hypertension<sup>3,4,9-11</sup> has received considerable attention, but suffice it to say that in carefully observed cases the incidence of postoperative hyphemia is no greater in those with high blood pressure than in those with normal arterial tension. The presence of diabetes<sup>3,10,11</sup> has long been thought to increase the chances of postoperative hemorrhage, yet DeVoe's analysis showed that in 40 diabetics bleeding occurred in 22.5 per cent, in contrast with 20 per cent in the entire group. My impressions are that hemorrhage does occur more frequently in diabetics, and that they are particularly prone to develop recurrent hemorrhages late in convalescence. Trauma is also considered a frequent cause of the hemorrhage, but this same author obtained a definite history of injury in only 8.4 per cent of cases with postoperative bleeding, a figure entirely consistent with my own experience. Vitamin deficiencies are much in the limelight as contributory factors in the production of hemorrhage into the anterior chamber, a suspicion which investigators have not been able to substantiate. If, however, a patient is obviously in need of these magic pills, no harm will result from their administration as preoperative and postoperative measures. Therefore, since we are unable to prevent this complication by these general measures, what can be done to lessen its incidence? I agree with Vail, who states, "The cause is, therefore, probably a purely local one."<sup>2</sup> Attention to the technical details both at the time of operation and during the convalescence are, therefore, of great importance.

Bleeding at the time of operation can be lessened by (1) adequate preoperative sedation, usually obtained by the use of 0.09 Gm. of nembutal an hour beforehand; (2) complete paralysis of the eyelids and thorough anesthesia accomplished by one of the standard methods of lid block, and by instillation of a local anesthetic plus subconjunctival and retrobulbar injections; (3) the avoidance of an unnecessarily large conjunctival flap; and (4) the placing of the incision at the limbus rather than in the sclera.

Hemorrhage during convalescence is also more prone to occur when the conjunctival flap is large and the section deep, particularly if combined with undue trauma at the time of the operation.

The role of corneoscleral sutures in preventing postoperative hemorrhages has been stressed by

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

From the Department of Ophthalmology, College of Physicians and Surgeons, Columbia University, and Institute of Ophthalmology, Presbyterian Hospital, New York City.

many authors, notably Stallard.<sup>12</sup> This writer reported no hemorrhages in 107 cases when this method of wound closure was employed, whereas previously he had seen it in 30-35 per cent of his cases. Equally enthusiastic approval of this method of reducing the frequency of this complication has been voiced by Lindner,<sup>13</sup> Leech and Sugar,<sup>14</sup> McLean,<sup>15</sup> Kirby,<sup>16</sup> and others,<sup>5,17</sup> while a more conservative estimate of its value is borne out by the analysis of DeVoe,<sup>3</sup> and by the statement of Ellett,<sup>18</sup> who says, "The freedom from postoperative anterior chamber hemorrhage which Mr. Stallard has enjoyed since adopting this suture has, I am sorry to say, not been my fortune. . . . I see such hemorrhages with unpleasant frequency in spite of this or any other form of suture." While the discussion still rages, it is my belief that in the final analysis proper coaptation of the wound edges will prove to be but one of many important factors in preventing postoperative hemorrhage. Removal of the corneoscleral sutures is a ticklish job which requires adequate anesthesia, good illumination, and delicate manipulation. Hemorrhage into the anterior chamber is not an infrequent complication of this maneuver when there is inadequate anesthesia or when the suture is grasped with the forceps before it is severed. Since it is now generally recognized that most hemorrhages into the anterior chamber come from the wound rather than from the iris, it behooves us to see that the edges are in proper apposition at the close of the operation, and to keep them that way during the healing period. This means not only a properly performed operation, but adequate postoperative nursing care. Included in the "musts" is the avoidance of a maneuver capable of producing pain at the time of the dressings or removal of the sutures. There has been considerable discussion of the relative frequency of hemorrhage into the anterior chamber in various types of operative procedures<sup>3-6,19,20</sup>—e.g., intracapsular and extracapsular extraction both with and without iridectomy. Time will not permit a review of these conflicting reports, but suffice it to say that no definite information is at hand that intraocular hemorrhage occurs more frequently with one method than with the other.

In spite of preventive measures, hemorrhages do occur and demand treatment. Usually even those that fill the anterior chamber disappear promptly under rest and atropine. Time and patience are required for some, but, judging from my experience, the vast majority need nothing more. Heat is contraindicated because it often increases the amount of bleeding and changes a mild case into a severe one. If the bleeding is severe enough to cause the wound to

gape and the iris to become prolapsed, we have to consider resuturing of the wound and excision of the prolapse. Recurrent hemorrhages into the anterior chamber occurring late in convalescence are usually from the iris and offer a more serious prognosis, but the treatment is essentially the same. Many authors have advocated all sorts of medications<sup>7</sup> to increase the clotting time of the individual, but in my hands they have not proved to be of value.

### Iris Prolapse

The occurrence of this complication is largely due to one of three causes:

1. Faulty reposition of the iris at the time of operation.
2. Improper closure of the wound.
3. Subsequent wound rupture.

The prevention of those prolapses occurring at the time of operation is self-evident. Proper reposition of the iris at the time of operation has been stressed since time immemorial, yet one still finds surgeons who hope that a miotic will draw the iris from the wound. In my experience this is not a safe procedure. When a peripheral iridectomy has been performed and the iris cannot be freed from the wound at the end of the operation, it is my practice to proceed at once with the completion of the iridectomy. Incarceration of the iris may also result from poor judgment in the selection of the type of iridectomy. I agree with Kirby<sup>16,21</sup> that in the presence of fluid vitreous or when vitreous loss can be anticipated a wide complete iridectomy should be done. If the peripheral iridectomy is reserved for the uncomplicated cases with mobile irides, the incidence of prolapses will probably be no greater in this group than in those who have a complete iridectomy.

Kubik<sup>19</sup> and others<sup>10</sup> feel that preservation of the sphincter muscle is helpful in preventing a prolapse of the iris. They argue that the vitreous is thus held in place by the contracted pupil, which in turn favors prompt restoration of the anterior chamber. While this condition may exist in certain instances, usually when the vitreous herniates forward the whole iris is carried with it toward the posterior surface of the cornea. A sufficiently large opening in the iris to allow the aqueous humor to pass from the posterior chamber into the anterior chamber is, to my mind, more important than the preservation of the sphincter muscle in reducing the number of iris prolapses.

Improper closure of the wound results from inclusion of foreign material, such as lens capsule or iris tissue, between the lips of the incision, or from faulty suturing. Such a wound may close temporarily only to open subsequently. It is this

secondary reopening that causes the iris to prolapse. We are all familiar with loss of the anterior chamber at the time of dressing or upon removal of the sutures. Such accidents can usually be avoided by attention to every minute detail of these maneuvers. I cannot stress too strongly the necessity for great care at the time of the first dressing. Pain from touching the upper lid or from exposure to bright light produces a violent blepharospasm often sufficient to rupture the wound, particularly one that is not properly sutured. The value of corneoscleral sutures in preventing this secondary wound rupture is widely accepted. Ellett,<sup>18</sup> Stallard,<sup>12</sup> Leech and Sugar,<sup>14</sup> and McLean<sup>15</sup> have all presented statistics corroborating the reduction in number of iris prolapses since using some form of corneoscleral sutures. The support afforded by such stitches is most reassuring, but even they do not make it impossible for the wound to open. A severe hemorrhage into the anterior chamber, a sudden squeeze of the eyelids, or increased intraocular tension, are all familiar causes of secondary wound rupture with or without corneoscleral sutures. There are diverse opinions on the treatment of iris prolapse. Some feel that its presence, no matter how small, demands immediate attention;<sup>5,19,21,22</sup> others, recognizing the hazards incident to early operation,<sup>5,8,10,19,23</sup> favor delay. Those who believe that emergency measures are necessary insist that if the iris is promptly replaced<sup>7,16,21</sup> and a 1 per cent solution of eserine salicylate instilled,<sup>10,11,22,23</sup> an iridotomy or iridectomy is often not necessary, an experience I have not had the good fortune to enjoy. Others advocate cauterization of the prolapsed portion of the iris using trichloroacetic acid<sup>6,8,16,24</sup> and carbolic acid or the actual cautery,<sup>8,16,21,22</sup> while many more favor excision<sup>17,19,21,23</sup> of the prolapse and the closure of the wound with or without a conjunctival flap as the occasion demands. Cauterized wounds are slow to heal and necessarily produce more scar tissue than a cleanly sutured one. Those who favor cauterization point to the ease and safety with which it can be done, reasonable arguments in the days when akinesia and retrobulbar injections were not in use. In nervous individuals, when even these measures are not entirely safe, pentothal sodium can be employed. The smooth and rapid anesthesia induced by this drug makes it ideal for use in these cases. It can be recommended, and wider use of this anesthetic agent in apprehensive, tense patients whose eyes are extremely sensitive will do much toward lessening the complications of this operative maneuver.

The decision of when to operate must remain an individual one. A small iris prolapse completely covered by conjunctiva can sometimes be

left alone, but one devoid of such a covering should, in my opinion, be promptly excised. Those larger prolapses with definite evidences of wound rupture usually demand prompt repair. The sequelae of an iris prolapse, viz., cystoid scar, updrawn pupil, secondary glaucoma, and sympathetic ophthalmia, are familiar to all of us. We recognize their seriousness, so let's do our best to prevent them by properly caring for all iris prolapses.

### Delayed Restoration of the Anterior Chamber

While the seriousness of this complication is universally recognized, it has not received adequate consideration. Since an ounce of prevention is worth many pounds of cure in dealing with delayed restoration of the anterior chamber, it behooves us to study its causes. Kirby<sup>16</sup> has mentioned among them such conditions as low general vitality, faulty body chemistry, and low eye vitality; but in my experience faulty operative technic is the chief cause. In some older patients the wound is a bit slower in healing, but these are the exceptions rather than the rule. The general condition of the patient, therefore, seems to have but little to do with it. The most important preventive measure is proper wound closure. This means not merely the introduction of properly coaptating corneoscleral sutures but careful toilet of the wound. In the extracapsular extraction particular attention must be paid to bits of capsule and lens matter which may become incarcerated between the lips of the wound. Such a happening is prone to occur with an unsuccessful attempt to extract the lens in its entirety. The capsule ruptures after the lens is dislocated below, and remnants of the capsule and lens matter remain in the upper part of the anterior chamber in contact with or actually incarcerated in the incision. "When such an accident occurs it is particularly important for the surgeon to free the wound of all such material. In the intracapsular extraction iris tissue is the chief object of concern unless, of course, vitreous has been lost. When the vitreous presents but the hyaloid does not rupture, it will usually recede in time, and the sutures can be tied without incarcerating any of it in the wound. A hasty attempt to close the wound may result in squeezing the prolapsed vitreous between the lips of the wound, thereby rupturing the hyaloid. I have found the simple request to the patient to close the eye helpful because the upward rolling of the eye tends to approximate the edges of the wound. This can be done without removing the speculum, and in a short time the vitreous recedes and the sutures can be safely tied. In some instances it

is wiser to remove the speculum and wait for a few minutes before proceeding with the tying of the sutures and the toilet of the wound. If, however, the hyaloid ruptures and some vitreous actually escapes I know of no way of preventing incarceration, and prompt closure of the wound is indicated.

There still remain a certain number of cases in which, in spite of proper suturing and adequate toilet of the wound, the anterior chamber does not reform. The iris is in position and no obvious defect exists, yet the days pass and the anterior chamber does not reform. Vail<sup>2</sup> believes spasm of the orbicularis is an important factor in these cases and advocates a vertical blepharotomy in the upper and lower lids. Girdle and Sugar<sup>24</sup> have also endorsed this procedure as a prophylactic measure. To my mind delayed closure is due to one of two possibilities:

1. The iris becomes adherent to the anterior face of the vitreous, a happening which is particularly prone to occur when an extraction without iridectomy has been performed although it can take place when a peripheral iridectomy has been done. Because of such an adhesion the aqueous humor in the posterior chamber cannot pass through the pupillary area to cause a reformation of the anterior chamber. Such a state of affairs calls for energetic efforts to dilate the pupil, for with its dilatation the interior chamber is often promptly reformed. It is my conviction that the instillation of a strong miotic, e.g., 1 per cent solution of eserine salicylate, at the time of operation, is contraindicated. It is irritating to the iris and extensive adhesions are more apt to occur when it is used. Furthermore if the vitreous has a tendency to herniate forward through the pupil at the time of operation, a strongly contracted iris may actually result in an incarceration of the vitreous in the anterior chamber.

2. A filtering cicatrix is present. This possibility has to be borne in mind in all cases where there is no other obvious cause for a delayed restoration of the anterior chamber. If such filtration can be established by the fluorescein test, I believe it is an indication for a prompt closure of the filtering cicatrix. Epithelization of the anterior chamber and secondary glaucoma are the expected outcomes of delay in dealing with this complication. Detachment of the choroid is often but another manifestation of this condition, and its persistence, along with an absent anterior chamber, should make one doubly suspicious of a leaking wound demanding closure. Such wounds are not always easy to close. In my experience covering the wound with a conjunctival flap drawn down from above after the method described by Kuhnt<sup>3</sup> is not always suffi-

cient. In addition, it is often desirable, after locating the small opening, to freshen its edges and close it with a suture before covering the wound with a conjunctival flap. Cauterization with carbolic acid, 60 per cent alcohol, or galvanometer, as advocated by Green,<sup>17</sup> has not, in my hands, been successful.

The consequences of delayed restoration of the anterior chamber may be enumerated as follows:

1. Corneal opacification
2. Peripheral anterior synechia
3. Adhesion between the anterior face of the vitreous and posterior surface of the cornea
4. Adhesion between the iris and the anterior face of the vitreous
5. Detachment of the choroid
6. Epithelization of the anterior chamber
7. Secondary glaucoma

Since most of these consequences predispose to the development of secondary glaucoma it is most important that a prompt restoration of the anterior chamber be effected. It is my belief that glaucoma occurring after cataract extraction usually arises from a delay in the reformation of the anterior chamber and that prompt attention to or prevention of this complication will do much to lessen the incidence of this dreaded aftermath.

### Summary

Hemorrhage into the anterior chamber usually occurs from the wound rather than from the iris. Unless it is very severe it clears without producing any serious effect upon the ultimate visual result. The proper treatment consists of complete bed rest and thorough atropinization. Hot compresses frequently do more harm than good.

Iris prolapse results from faulty reposition of the iris, defective wound closure, or subsequent wound rupture. Corneoscleral sutures do much to prevent its occurrence. Prompt excision of all prolapses is the rule, with the possible exception of small ones adequately covered by conjunctiva.

Delayed restoration of the anterior chamber usually means either faulty wound closure or the presence of a filtering cicatrix. Proper toilet of the wound and adequate sutures are our best prophylactic measures. Prompt repair of all leaking wounds will lessen the incidence of epithelization of the anterior chamber and postoperative glaucoma.

## Discussion

Dr. E. Clifford Place, *Brooklyn*—For the purpose of this discussion I analyzed 100 recent operations for cataract in my service in the Brooklyn Eye and Ear Hospital. They comprised private as well as clinic cases and were performed by various operators—by myself, and by members of the resident and of the attending staff. Fifty-five were intracapsular extractions, 35 were extracapsular, of which 12 were attempted intracapsulars, 6 were linear extractions, 1 loop, 1 Homer Smith, and 2 dissections of secondary membranes.

The following complications occurred in this series, during the operations or convalescence.

The capsule ruptured in the 12 cases noted above in which the cataract was safely removed by the extracapsular method.

Iris prolapse occurred in 3; all were small.

Hemorrhage of all grades occurred in 10. Some of these occurred at the time of operation, from the wound; in 3 there was a history of trauma from the patient, and the majority of those occurring after operation appeared from the fourth to the sixth day, a time interval which is in line with the reported experience of others. In only one of these cases was diabetes present, and in only one was there high blood pressure—240 over 106—and this was one of those associated with trauma. So it appears that neither of these constitutional states was a prominent factor in this group. All these hemorrhages absorbed and a satisfactory visual result was obtained, with one exception.

There was delayed formation of the anterior chamber in 4, in 2 of which the chamber was flat until the ninth day. All finally filled without the need for active treatment. There was striate keratitis in 16, and all cleared before the patients left the hospital; iritis in 2; vitreous loss at operation in 3. One of these was a dislocated lens in the case of loop extraction, and a second was in a high myope with fluid vitreous. In both of these vitreous loss was expected before operation. One patient vomited persistently, ruptured her wound, and suffered iris prolapse and hemorrhage. This was the one

patient mentioned above who did not obtain a good visual result. As a matter of fact, she died of coronary occlusion a few days after operation; this diagnosis was confirmed by autopsy. In one case operation apparently precipitated thrombosis of the central retinal vein, for it was not present shortly before operation on an immature cataract.

One suffered acute urinary retention.

Two developed corneal dystrophy, and both cases cleared up with administration of Dr. Dunnington's magic vitamin capsules.

One had dermatitis of the lids, probably from use of bichloride ointment on the pads.

Five choroidal detachments were noted—there may have been more.

One retina detached promptly after intracapsular extraction, with a big tear, and one patient developed meningitis and wound infection.

In one dacryocystectomy was performed before the cataract operation, and the latter healed without infection.

This sounds like a formidable list, but on looking it over it appears that most of these complications were minor in character, and only a few more serious; many were not preventable, while some were.

It seems to me Dr. Dunnington has wisely chosen the three complications of greatest importance, from the viewpoint of their seriousness to the future of the eye as well as of their preventability.

To be sure, my own attitude toward most cases of anterior chamber hemorrhage is much like that of Vail, who regards it as midway between serious and trivial. The single hemorrhage may be trivial even though it be a generous one, but none of us can regard with unruffled equanimity the recurrent cases which we sometimes meet. Certainly trauma plays a part, and it is equally certain that in the single hemorrhages with or without trauma, the source of the bleeding is the wound itself and not the iris. I once had the disagreeable experience of seeing blood run down from the wound into a chamber because at a dressing the lower lid was touched with sufficient force to cause a slight rupture of the wound. Yet in another case in which the man fell out of bed with force enough to fracture his humerus no ocular complication whatever developed. Hemorrhages will continue to occur in this, one of our major ophthalmologic operations, but I agree with Dr. Dunnington that accurate placement of the section and tight suturing are important aids in its prevention.

I should like further to emphasize his admonitions about not grasping the suture with forceps when attempting its removal. The prestidigitator says "The quickness of the hand deceives the eye," but it is apt to be the other way around, when a patient suddenly jerks his eye upward when you have a grip on a suture. I know of one case in which the wound was ripped wide open in this manner, with loss of considerable vitreous.

Iris prolapse has for me much more serious connotations. Sympathetic ophthalmia can and does occur, in both treated and untreated cases, and much more frequently glaucoma develops. Even complete iridectomy does not prevent prolapse, for a pillar may force itself into the wound and become

incarcerated, to be discovered at the first dressing or subsequently. It is in this connection that I fear postoperative vomiting more, I think, than anything else. Before the days of suturing I saw more than one eye whose contents were expelled during the first postoperative night by uncontrollable vomiting, and now even with sutures I still fear it, for it is in these cases I find most of my cases of iris prolapse. It seems impossible in the strain and stress of prolonged vomiting to avoid squeezing the eyes. I feel, however, that with improved methods of preoperative sedation, avoidance of giving anything by mouth for at least twelve hours after operation, and the use of codeine by hypo—never morphine—for postoperative pain, we have reduced the frequency of postoperative vomiting, and we do have fewer cases of severe iris prolapse. Of course, suturing plays a huge part.

Is it not possible that in some instances spasm of the orbicularis occurs during the time of recovery from the akinesia, thus producing pressure on the globe sufficient to produce some prolapse? Vail speaks of the "constitutional moment" in which the slightest pressure by the lids or movement of the eye might reopen the wound, with resulting hemorrhage or iris prolapse. Since a well-closed cataract wound seals itself almost immediately with prompt restoration of the chamber, it is conceivable that this "moment" may, in some cases, occur early enough to produce these complications sooner than in others.

My practice is to treat small prolapses which are covered by conjunctiva with trichloroacetic acid, and to excise the larger ones and close, either with a flap or with direct suturing. To leave a bulky incarceration of the iris is to invite not only a poor visual result from high astigmatism, but far more serious, the development of secondary glaucoma, which is so unsatisfactory to deal with.

I am glad Dr. Dunnington mentioned pentothal anesthesia. I have . . . a variety of eye . . . extending its use . . . in our work.

It has been my good fortune not to see the serious type of delayed chamber formation of which Dr. Dunnington speaks. True, cases of delay occur, and many are accompanied by choroidal detachments. Formerly these detachments worried me considerably and I kept the patients in bed until they subsided. Now I have even sent them home from the hospital with the detachment present, so long as the chamber was even partially restored. I have never seen one that did not subside satisfactorily—often abruptly overnight—though in one case of trephining for glaucoma, in an elderly patient, it lasted for months.

I should like to ask Dr. Dunnington how many days he thinks it advisable or safe to wait before considering active surgical interference in cases of delayed restoration of the chamber.

To my mind, the two greatest advances in the past few years in the prevention of complications in cataract surgery are the more universal adoption of paralysis of the orbicularis and the use of sutures to

close the wound. These, with meticulous attention to every detail of technic before, during, and after the operation, help to assure, now more than ever, a satisfactory result in this, ophthalmology's most interesting surgical procedure.

Dr. Ivan Koenig, *Buffalo*—A discussion of a paper written by Dr. Dunnington on the phases of cataract complications is like discussing the gospel, because of its authoritative veracity. There are other complications of cataract surgery that could be mentioned, but inasmuch as the paper refers to only three important ones, these few minutes will be devoted only to those phases.

Hemorrhage into the anterior chamber is not, as a rule, a serious complication. Most of these hemorrhages absorb quite readily and in no way interfere with the visual result, but in order to stress the importance of postoperative hyphemia, I should like to cite briefly a case of my own. A man, aged 64, had an uncomplicated intracapsular extraction with a small peripheral iridectomy. There was a moderate arteriosclerosis without hypertension or any pathologic finding which would contraindicate an extraction or make one expect any serious complication. At the first dressing the wound was in apposition; the anterior chamber was reformed; no prolapse or incarceration of iris was observed. He was allowed out of bed on the fourth day. Late the same day a small hyphemia was noted. He was ordered to bed but the orders were not carried out and on the fifth day a large hematoma was noted at the wound and the anterior chamber was filled with hemorrhage. To make a long story short, an enucleation was performed on this eye six months later because of a secondary glaucoma.

This case is cited because it is my firm belief and my practice to recognize a hyphemia and respect it with immediate rest in bed until absorption has at least begun. I agree with the essayist that hot applications are liable to do more harm than good. Magic pills, too, have been tried, but I still see anterior chamber hemorrhages. It has been my good fortune, or shall I say misfortune, to observe anterior chamber hemorrhage develop, while I was examining the eye with a hand slit lamp. The bleeding in this case came from the wound above and not from the iris and developed on the sixth day.

The occurrence of anterior chamber hemorrhage in my cases is not as frequent nor as severe, since I have discontinued making conjunctival flaps, either previous to incision or those made with a Graefe knife. My incisions are now made at the limbus with a keratome and enlarged with scissors. In this way there is practically no conjunctival flap and the insertion of a corneal episcleral suture seems less complicated and more secure.

The report of Stallard that in 107 cases no anterior chamber hemorrhage occurred is nothing short of phenomenal. He attributes this to his suture, which is supposed to bring about better coaptation. Dr. Dunnington states that this may be the answer to this problem, but other factors enter into it. I agree with him, and am reminded of a statement once made by Dr. James White in regard to sutures for muscle operations. He read a paper in which

he stated: "Breathes there an ophthalmologist who, during some attack of insomnia, has not thought up an original stitch or muscle operation?" A statement similar to this can apply to the various sutures used by various operators in cataract cases. It is my feeling that the more complicated the suture the greater the possibility of complications developing in either the operative or postoperative period. In reviewing the last 100 cases of cataract extraction I have done, I found that hemorrhage occurred more frequently at night and usually after the fourth and before the seventh postoperative day. In this small series I found 21 cases of anterior chamber hemorrhage.

The question of iris prolapse has not been as frequent a complication since the use of firm corneal episcleral sutures. I have seen only one case of iris prolapse in my last 100 cases, and this a week ago. There were a few cases of iris incarceration but only one visible prolapse. Thomas Allen, of Chicago, in discussing this condition, said, "Prolapses sometimes occur in the best of hands but many of them indicate poor surgery." It should be remembered that even though well-placed sutures have reduced the incidence of iris prolapse, I wish only to re-emphasize Dr. Dunnington's warning about false security of sutures, when doing the first few dressings. It may not be common for visible prolapses to occur during the dressing, but I feel that iris incarcerations develop at this time more frequently than we admit. My feeling is that iris prolapses that are not covered with conjunctiva should be taken care of within twenty-four hours. There have been times when this has occurred that I have made the repair in the room of the patient rather than the operating room for the psychologic effect on the patient. Surgical excision has usually been my approach to this condition. Cauterizing with either chemical, thermal, or coagulating agents is apt to cause more iris reaction.

At this point I think it worth emphasizing the purpose of the iridectomy. Whether you make a complete iridectomy or a peripheral iridectomy it is necessary to make "A large enough opening in the iris to allow the aqueous to pass from the posterior to the anterior chamber." This practice of the essayist will help prevent many prolapses and incarcerations of the iris.

Delayed formation of the anterior chamber, fortunately, does not occur often. Theoretically, it should develop more frequently following an extracapsular extraction, because of capsular and cortical material's getting in the wound. I recall one case that developed after the first dressing and remained long enough for anterior synechia and subsequent secondary glaucoma to develop. This only re-emphasizes the warning given by Dr. Dunnington about the first dressing.

To search for one cause for this complication in all cases will reveal a series of them. Many reasons could be cited to refute some of the theories of delayed anterior chamber formation.

Orbicularis spasm has been cited as a cause of this complication by Vail, Gradle, and Sugar. I recall two such cases in which blepharotomy was done because of deeply recessed globes; both chambers refused to form for several days. Orbicularis spasm or involuntary postoperative squeezing may be a factor, but I do not feel that blepharotomy will prevent it.

It would seem to me that the adhesion formation of the iris is the result rather than a cause of anterior chamber collapse and that these adhesions are the result of a leaking wound.

To repair such a leaking wound would be simpler if this area could be found without too much manipulation. The greatest problem in such cases is to have an area that is leaking, large enough to be visible, inasmuch as the slit lamp can't be used on early postoperative cases.

Dilatation of the pupil is one of the greatest aids in the reformation of anterior chambers. It should be remembered that the mere instillation of daily atropine may not be sufficient. Neosynephrin hydrochloride or adrenalin packs following cocaine instillation give a more efficient dilatation in collapsed chambers, along with the atropine.

Apprehension on the part of the patient can repeatedly reopen the wound and to relieve this apprehension, I feel that sufficient barbiturates are invaluable.

Dr. Dunnington's paper stressed three very important complications of cataract surgery which should not only illuminate us but should stimulate us all to diligently seek the real answer to these and other cataract problems.

#### LOUIS LIVINGSTON SEAMAN FUND

The New York Academy of Medicine announces the availability of the Louis Livingston Seaman Fund for the furtherance of research in bacteriology and sanitary science.

One thousand dollars is available from the fund for assignment in 1944. This fund has been made possible by the terms of the will of the late Dr. Louis Livingston Seaman, and is administered by a Committee of the Academy under the following conditions and regulations:

1. The Committee will receive applications

from either institutions or individuals up to November 1, 1944. Communications should be addressed to Dr. Wilson G. Smillie, Chairman of the Louis Livingston Seaman Fund, 1300 York Avenue, New York 21, New York.

2. The fund will be expended only in grants-in-aid for investigation or scholarships for research in bacteriology or sanitary science. The expenditures may be made for securing of technical help, aid in publishing original work, or purchase of necessary books or apparatus.

## CALCIFIC DEPOSITS IN THE SHOULDER\*

HARRISON L. McLAUGHLIN, M.D., New York City

**D**URING the past decade a considerable number of sore shoulders have been studied by the Fracture Service of the Presbyterian Hospital in New York. Included were more than 1,500 cases in which the symptoms centered around a calcific deposit. Of the latter group, various series of cases were subjected to almost all the many forms of therapy advised for the condition and the results were compared with several hundred control cases in which no or only sedative therapy was employed. The striking similarity between the results of the control cases and those of the cases treated by all but a few of the available therapeutic measures prompted analysis of the pathology observed at operation and its relation to the clinical behavior of the condition.

Gross, microscopic, and bacteriologic examinations of the pathology found in a considerable number of lesions explored in various stages of the disease have made it possible to reconstruct what might be termed the life cycle of the so-called "calcified deposit" and its resulting syndrome, commonly called "calcified bursitis." As Codman<sup>1</sup> has pointed out, the deposit is neither calcified nor is it in the bursa.

### Origin

The earliest microscopic evidences of the lesion consist of hyaline degeneration in the collagen of the tendon fibers. This is followed by fibrillation and the formation of what Codman called "straps" or loosened bands of fibers within the substance of the tendon. Motion of the part plus progression of the degenerative change further loosens these strands, finally breaks them free from their attachments to the surrounding more normal tendon, and grinds them into rice-like bodies occupying a small cavity within the tendon substance. Continued motion aided by necrosis continues to grind the rice-like fragments into progressively finer particles until the material in the cavity comes to resemble the contents of a wen. Such collections of tendon debris showing no opaque shadow by x-ray have been encountered not infrequently in the course of shoulder operations done for other conditions.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

From the Fracture Service of the Presbyterian Hospital in New York, and the Department of Surgery, the College of Physicians and Surgeons, Columbia University.

<sup>1</sup> Codman, E. A.: The Shoulder: Rupture of Supraspinatus Tendon and Other Lesions in or About the Subacromial Bursa, Boston, 1934.

### Course

How, when, or by what mechanism calcium salts are deposited in this debris in sufficient concentration to produce a shadow by x-ray is not yet understood. There is no reason to believe this mechanism to be any different from that resulting in the deposition of calcium salts in an old tuberculous node where the matrix is formed by caseation necrosis of lymphoid tissue rather than by degenerative necrosis of tendon tissue. It is possible that such nodes if subjected to the same factors present in the short rotators of the shoulder might also produce irritative phenomena resulting in inflammation and pain.

The symptoms associated with calcific deposits (which may occur in any tendon and have been found in most) are the result of an inflammatory reaction situated in the vascular peritendinous structures adjacent to the tendon involved rather than in the tendon itself. In the short rotators of the shoulder the tendon sheath is represented by the floor of the subdeltoid bursa. Therefore, while deposits in most other tendons produce a tenosynovitis, shoulder deposits produce a subdeltoid bursitis. The histologic pathology of this inflammatory reaction is not extraordinary except for the rather constant presence of giant cells which most investigators agree represents a response to foreign body in the tissues. Bacteriologic studies all have been negative for aerobic and anaerobic organisms and for filtrable virus. Therefore it seems logical to conclude that the inflammation, per se, constitutes a foreign-body reaction to irritation by the contents of the deposit.

The deposit, whether or not it contains enough calcium salts to show up by x-ray, constitutes a foreign body which nature normally would attempt to eliminate by the institution of an inflammatory reaction. This may be the explanation for some of the acute conditions in shoulders having no calcific shadow to account for their symptoms. For the mobilization of any inflammatory reaction the *sine qua non* is adequate circulation. In its early stages the deposit is within the substance of the almost avascular tendon, under which circumstances a minimal reaction, if any, is possible. This fact is the basis for the only logical explanation of what has been one of the most puzzling features of the condition—i.e., the commonplace incidental finding of a calcific deposit by x-ray in the complete absence of any past or present symptoms. Such quiescent lesions are considered to be those in which

FIG. 1

the deposit is buried deeply enough in tendon tissue so that no peritendinous (bursal floor) irritation takes place.

When it is possible to follow such quiescent lesions it is found that a great many of them eventually develop symptoms in some degree and it is reasonable to assume that most painful lesions were at some early stage quiescent. Symptoms may come on suddenly or gradually. The latter are usually mild in character and may be constant or intermittent, whereas the former are usually acute and constant. Regardless of their character, it has been adequately demonstrated that the occurrence of symptoms coincides with and results from the initiation of the peritendinitis, or bursitis, as it is usually called. This inflammatory phenomenon takes place when the material in the deposit works through the overlying tendon and comes into physical contact with the adjacent vascular tissue. Several factors are constantly at work toward this end.

1. The tendon substance overlying the deposit in the shoulder and separating it from the floor of the bursa is the seat of progressive degeneration and weakening due to attritional causes.

2. The constant milking action exerted upon the material in the deposit by movement of the tendon under the edge of the acromion and coraco-acromial ligament tends to force it in the path of least resistance—i.e., through the overlying tendon in the direction of the bursal floor (Fig. 1).

3. Use and motion of the extremity and especially overuse or sudden strain may rupture the weakened tendon fibers overlying the deposit.

Inasmuch as the amount and degree of inflammation and, ipso facto, the character of the symptoms depend upon the amount of foreign-body irritant involving the synovial tissue at any one time, the acuteness or chronicity of any case will be affected if not governed by the relative prominence of any one of these three factors. If progressive degeneration of the overlying tendon

allows only a few particles of the deposit to work through at a time, the symptoms will be mild and commonly intermittent. If a rupture of the overlying fibers allows a major portion of the deposit suddenly to come into contact with the under surface of the bursal floor, an acute attack will almost certainly follow.

A great many chronic cases are marked by intermittent exacerbations of pain alternating with quiescent periods. Occasionally this goes on for years. It is apparent that the exacerbations are the result of a few particles of the deposit having worked their way through the overlying tendon to set up a small peritendinous reaction beneath the floor of the bursa. Eventually these particles are disposed of by polymorphonuclear action, the reaction subsides, and the opening in the tendon becomes sealed over by fibrous tissue. This process may be repeated at intervals until the deposit is eliminated by continued depletions or an acute attack may supervene. The implication behind the clinical behavior of repeated mild attacks is that absorption of the material is possible by inflammatory action alone if the amount of material to be absorbed is small. As will be seen in the following discussion, this method of eliminating the deposit differs somewhat from that observed in the ordinary acute case.

Certain painful shoulders due to irritation by a calcific deposit tend to stiffen. Whether the disease be acute or chronic, this will always happen in some degree when the normal function of the extremity is unduly restricted by sling, swathe, bed rest, or voluntary inaction on the part of the patient. Experience has shown neither sling nor any other form of functional restriction to be indicated except as a temporary sedative measure during the acute phase of the condition. It is of utmost importance that mobility of the part be maintained during all other stages of the disease because otherwise the inflamed floor of the bursa quickly adheres to the apposed bursal roof, sometimes to the extent of complete obliteration of the bursal cavity. Such adherence of the walls of the bursa superimposes one of the conditions commonly termed "frozen shoulder" upon the pain resulting from the calcific deposit to make the therapeutic problem much more difficult. Acting in this way, the deposit constitutes only one of the many causes of frozen shoulder, all cases of which present approximately the same clinical picture although different pathologic findings, depending on the primary cause of the stiffness. In those having a calcific deposit as the primary cause, adhesive bursitis has been a constant operative finding and a rather major factor in the production of stiffness. In frozen shoulders due to other causes

the bursa may be innocent of any pathologic change.

The character of the pain in chronic calcific esions is apt to vary. It was formerly difficult to understand why, in two cases having deposits of equal size and consistency by x-ray, one should suffer from a constant ache and the other from nothing more than a catch of pain on certain motions of the arm. Operative findings have demonstrated that the character of the symptoms are governed to some extent by the position of the deposit. Lesions in the subscapularis seldom produce chronic symptoms and tend to remain quiescent until an acute attack occurs. In the supraspinatus and anterior part of the infraspinatus a constant ache is the rule during the chronic stage. In the posterior part of the infraspinatus and *teres minor* the chronic stage is apt to be characterized by sharp catches of pain in certain positions. Under both local and general anesthesia it has been demonstrated clearly that pain is aggravated by tension of the tendon host but becomes acute when the inflamed tissue superficial to the deposit is squeezed against the under edge of the acromion or coraco acromial ligament. Consequently it is logical that a lesion in the superior portion of the cuff, where it is under constant tension by gravity and brushes against the acromion at almost every movement, should produce more severe and constant symptoms than one in the anterior or posterior part of the cuff, where impingement is possible only in certain extreme positions of the arm and where gravity plays a relatively minor role.

Many acute attacks are preceded by chronic complaints, while many others deny antecedent symptoms. Some follow strain or overuse, while others are without demonstrable cause. Regardless of the mode of onset, operative findings constantly have demonstrated a common factor that seldom if ever is observed in the chronic case—i.e., a large quantity of the deposit in contact with the synovial floor of the bursa, surrounded by a correspondingly large and acute inflammatory reaction.

### The Acute Lesion

The commonly encountered "acute bursitis" is, with few exceptions, the result of reaction to a calcific deposit. The only macroscopic or microscopic differences between the acute and chronic lesion are:

1. The degree and extent of the inflammatory reaction.

2. The consistency and tension of the material in the deposit. At first glance it would seem that the quality of the material differed in the two phases. In the chronic stage it is dry, cheesy, or *wen-like* and tends to be infiltrated

through the tendon within a relatively poorly circumscribed cavity. In the acute stage it is invariably wet, greasy, and commonly the consistency of toothpaste. In addition it is under distinct tension within a rather well-defined cavity, from which it is apt to spurt when an incision is made into it. This change is also apparent by x-ray, where the chronic lesion is usually represented by a rather dense shadow with irregular or ill-defined borders and the acute lesion by a well-defined, globular, frequently flocculent shadow of less opacity. Operative findings have demonstrated this change in the physical and x-ray characters of the lesion to be the result of nothing more than infiltration and dilution of the dry chronic deposit by inflammatory exudate. In addition to the infiltration and dilution, the main factor causing increased tension in the deposit appears to be swelling of the adjacent tissues.

Continued inflammatory response leads to progressively increasing tension within the deposit. At this stage the lesion looks exactly like a furuncle presenting in the bursal floor. It also behaves like a furuncle in that internal tension eventually (usually within a week or two) reaches a point where rupture takes place. Unlike a furuncle, the contents are disgorged into the closed cavity of the bursa. Here they are quickly enmeshed in a network of fibrin, set upon by leukocytic action, and within the course of a few days are eliminated to such an extent that no further shadow is visible by x-ray. The worst part of the acute pain disappears with the release of tension following rupture. The residual pain disappears within a short time following disposal of the disgorged material and subsidence of the inflammatory reaction. A single deposit ordinarily results in only one attack of acute pain and it is rare for any subsequent symptoms to occur once the attack is over. Multiple deposits, on the other hand, are potentially prone to result in repeated acute attacks. This is apparently because each individual deposit goes through the various stages of its own life cycle independently of and uninfluenced by the others. The result, as has been observed not infrequently, is that a patient may recover from one attack either spontaneously or under some form of treatment and have the offending deposit disappear, only to suffer from a subsequent attack or attacks due to the remaining deposits.

### Prognosis

The condition appears to be self-limiting, with nature eventually attending to the spontaneous elimination of each deposit in one of two ways—i.e., gradual depletion by repeated inflammatory responses of mild degree each one of which disposes of a small portion of the material, or sud-

den and complete elimination of the whole deposit by rupture and discharge of the contents into the bursal cavity. As a result, the prognosis for eventual recovery from any particular attack is reasonably good, regardless of the type of treatment, at times in spite of it, or even if the condition is untreated. No permanent defects or disabilities have been noted except for the occasional complaint of recurrent rheumatic pains in the region, usually associated with bad weather or overuse. It is, however, reasonable to assume that fibrous tissue replacement of the deposit area predisposes to local weakness in the tendon, which more easily may become the site of rupture in later years. Because of its self-limiting characteristics, the therapeutic problem presented by this lesion therefore concerns not the question of recovery but speed of recovery.

### Therapy

There are only two available types of therapy, palliative and curative. There are only two forms of therapy simulating nature's method of cure and having proved curative effects, opening of the deposit by knife or needle. Other methods are chiefly palliative or empirical in effect and their professed curative powers when examined in the light of the known pathology and compared to adequate controls have been disproved or found to be empirical or indirect and uncertain. Purely sedative measures act to minimize the severity of the symptoms until nature effects a cure, whereas the various analgesic or local anesthetic procedures act to obtain temporary mobility of the part which, with good luck, results in rupture of an acute lesion.

### Needling Procedures

Various needling technics, including regional infiltration, irrigation of the bursa, multiple puncture, and aspiration of the deposit, have been practiced in sufficient quantity to allow adequate evaluation. Of these, puncture and aspiration of the deposit has been the only method constantly productive of certain and speedy relief of symptoms. Others may be followed by a speedy cure in the acute lesions but analysis indicates such results to depend upon either unpremeditated rupture of the deposit by the needle, rupture in consequence of the temporary mobility made available by the novacaine, or coincidental spontaneous rupture. Aspiration of some of the deposit is aimed for not because it is essential to the success of the procedure but because it serves to inform the operator that he has accomplished his main purpose—i.e., puncture and deflation of the deposit. Irrigation, per se, has no direct effect upon the speed of cure. More than 500 acute cases have been treated by aspiration. In

those patients who had an adequate procedure done, as evidenced by the appearance of calcific particles in syringe or irrigated fluid, immediate relief was the rule and complete cure within a five-day period was a constant result. The only recurrences have been in cases of multiple deposits.

Needling was tried in several hundred chronic cases. Temporary relief was obtained in less than 50 per cent and permanent relief in less than 25 per cent of all such cases. In the light of the known pathology these poor results are reasonably explained by the fact that the chronic deposit is physically not amenable to aspiration by needle. Even when such a deposit is opened by the needle, its cavity again becomes sealed off from the bursa after a small portion of the calcific material has been eliminated. Any attempt to aspirate the contents of a chronic deposit is inadvisable because of the physical characteristics of the lesion under ordinary circumstances.

### Operation

More than 100 cases have been explored and the deposit removed. The results are certain and complete relief follows more rapidly than with any other method of treatment. Removal of any additional deposits, as well as the offending deposit, lessens the risk of subsequent attacks of pain. Some of these additional deposits may be situated out of reach of a needle. The operative procedure is a minor one and may be carried out under local anesthetic, but is much more easily and efficiently completed under a light general anesthesia. More than two to five days' postoperative hospitalization or disability is uncommon.

Operation is indicated in only a small percentage of cases. It is most strongly indicated in chronic lesions when the pain or disability is sufficient to make it worth while from the patient's point of view, and in acute cases showing multiple deposits. It is occasionally imperative in acute cases not amenable to aspiration, the symptoms of which are jeopardizing the course of a precarious pregnancy or systemic disease. Occasionally it is resorted to following failure of a needling procedure. The cases operated upon included all phases of the condition and the pathology observed in conjunction with the clinical behavior of a considerable number of similar cases in which operation was not performed forms the basis for the statements made in this report, and it also forms a basis for the logical evaluation of therapy in calcific lesions:

1. It is first determined whether the symptoms by reason of their severity, duration, or resultant disability warrant curative or purely palliative measures.

2 Regardless of the answer to paragraph 1, mobility and function of the extremity must be maintained at a maximum, by a program of exercises if necessary.

3 If the condition is chronic and the circumstances warrant curative therapy, operation is the method of choice, aspiration by needle is a poor second choice, offering only about a 25 per cent chance of success, and palliative therapy, including all forms of physical therapy, radiotherapy, or administration of oral or parenteral drugs, does little except temporarily lessen the symptoms.

4 If the condition is chronic but does not warrant curative therapy, home measures, including heat, aspirin, and a program designed to maintain mobility of the arm are usually just as efficient as anything that can be done in office or hospital.

5 If the condition is acute, curative measures are warranted. The method of choice is aspiration of the deposit by needle, followed by a program of exercises and sedation. Exception to this choice of treatment should be considered when multiple deposits are present or when any other indication for operation is present.

## BICIPITAL TENOSYNOVITIS

ROBERT K. LIPPMANN, M D, New York City

**P**ERIARTHRITIS, now more generally known as frozen shoulder, was originally described by Duplay<sup>1</sup> in 1898 and so was removed from the vague classification of arthritis. Duplay ascribed the pain and stiffness that characterize the condition to an adhesive inflammation of the subacromial bursa and recommended brisement forcé for its cure. This concept and therapeutic approach have persisted for almost fifty years in spite of meager pathologic support. Our surgical studies, as reported in the *Archives of Surgery*,<sup>2</sup> have revealed subacromial bursa inflammation in only a few of these cases. Instead tenosynovitis of the long biceps tendon and sheath was consistently encountered. This present paper summarizes these studies and their clinical application.

### Clinical Data

It is not generally appreciated that periarthritis, or "frozen shoulder," runs a well defined and typical clinical course—that it is not merely a stiff, painful shoulder requiring therapeutic mobilization. A remarkable feature of this illness is its inevitable spontaneous cure. I am sure the reader will have difficulty in recalling a case of frozen shoulder presenting a history longer than one year, and our records indicate that the illness generally lasts approximately ten months. Wide variation occurs, however, and the duration may vary anywhere from three months to two years.

According to our records it is the commonest of shoulder conditions, affecting chiefly women (65 per cent). It occurs most often in those between the ages of 40 and 60, but it has been en-

countered in patients as young as 25 and as old as 80. Trauma is not generally the precipitating cause, the majority of patients describing an insidious onset. For some unknown reason, possibly postural, the condition is surprisingly common in association with invalidism and particularly with chronic cardiac and pulmonary disease. Another remarkable attribute of this condition is the failure of recurrences to develop. Bilateral periarthritis is not particularly uncommon, but a recurrence in the same shoulder has not been encountered in either hospital or office experience.

### Symptoms

The typical case of periarthritis, or frozen shoulder, commences with a mild ache in the shoulder or arm, which grows inexorably worse and is accompanied by progressive stiffness. The pain grows in intensity, becoming almost insufferable, and the stiffness slowly increases to the point of almost complete scapulohumeral fixation. After months of growing distress (often increased by scalene spasm and pain down the arm), the pain starts to abate and shoulder motion begins to improve. Undulant progress continues until the shoulder is again clinically normal. During the period when the disease is progressing, the pain dominates the picture. In the period of improvement, stiffness is the most prominent complaint.

### Examination

Examination of the patient quickly reveals the curious and typical fixation that characterizes the condition—free and painless motion within a limited arc, severe pain when the limits

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

FIG. 1. The tendon sheath of the long biceps tendon is open above and communicates freely with the joint. The shoulder joint distended with wax (from Gray's anatomy).

are forced. Universally there is sharp tenderness over the bicipital groove and absence of tenderness over other aspects of the shoulder proper. The constancy of these findings is of great help in distinguishing the frozen shoulder from other conditions commonly involving that joint.

### Differential Diagnosis

The painful shoulder caused by calcified deposits is practically never stiff. In this condition the voluntary spasm of the shoulder musculature can be easily overcome and full shoulder motion may be obtained, though it is painful. Since the seat of the calcified deposit is usually in the musculotendinous cuff, the area above the greater tuberosity is exquisitely tender but the bicipital groove is not painful on pressure. I mention x-ray last in differential diagnosis, for I have encountered typical cases of frozen shoulder diagnosed incorrectly and mistreated because symptoms were attributed to a small and innocent fleck of calcium visualized in the supraspinatous tendon.

Musculotendinous cuff tears, in contrast to frozen shoulder, generally exhibit tenderness directly over the cuff area. In tears of the cuff passive elevation of the shoulder is unrestricted, while active elevation is painful, weak, and limited. In frozen shoulder this differential does not exist, active and passive elevation being blocked and painful essentially at the same level.

### Anatomy

The long biceps tendon possesses a few peculiarities which might account for its role as a trouble-maker in peri arthritis and which merit a brief review.

Anatomically, the biceps tendon sheath differs from other similar structures in the body by being closed only at the bottom. Its upper end communicates freely with the shoulder joint proper (Fig. 1). Moreover, the tendon slides freely between the joint and the sheath upon motion of the shoulder (Fig. 2). These observations show how easily inflammation can extend from the sheath below up and into the outer quadrant of the shoulder joint.

FIG 2 The bicipital tendon slides freely between sheath and joint proper as the shoulder is moved. A—Ventral position B—Elevation C—Internal rotation D—External rotation

It is of considerable importance to appreciate the fact that the long biceps tendon does not move in its groove in response to pull of the muscle to which it is attached. Motion of the biceps tendon in its groove occurs only on motion of the shoulder joint, and the biceps muscle performs a minimal role in producing motion of this joint. For this anatomic reason, an inflamed biceps sheath hurts when the shoulder is moved, whereas it does not hurt on elbow motion, which utilizes the biceps muscle. Briefly, the long biceps tendon mechanism is a passive one and is important only as a source of trouble when it functions improperly.

### Surgical Studies and Findings

The constancy of bicipital groove tenderness in frozen shoulder and the foregoing physiologic observations appeared to justify surgical investigation of this mechanism. Up to May, 1944, 32 cases of frozen shoulder had been so studied.

In all instances the subacromial bursa and underlying musculotendinous cuff were carefully explored and their condition noted prior to exploration of the biceps sheath mechanism. A short, deltoid splitting incision gives free access to these structures as well as to the biceps sheath. Individual case findings have been reported elsewhere. They have been so uniform, however, that it will serve present purposes best to discuss them together. In two cases tears of the cuff

FIG 3 Summary chart showing the differences encountered in cases operated upon early and late in the course of the illness.

were encountered, one partial and one complete and in these cases secondary changes were noted in the overlying subacromial bursa. In both of these cases cuff tears were suspected prior to operation by the above described clinical criteria. In two cases, bursal adhesions without cuff tears were encountered. In all other cases the appearance of the synovia of the subacromial bursa was smooth and glistening. The sac contained no fluid and there were no adhesions. The underlying musculotendinous cuff was entirely normal. On the other hand, all explored cases showed inflammatory changes of varying degree involving the biceps tendon and sheath. Moreover, in practically all the cases studied, there was a variable degree of impairment of motion of the biceps tendon in its groove caused by peritendinous adhesions. For purposes of classification it was found useful to divide our preoperative material roughly into two clinical groups—early and late cases—i.e., cases selected for operation during the stage of progressively severe pain and stiffness and those in the later phase during which stiffness was the chief complaint. As might be assumed, more of the early cases were available for exploration because of the more severe pains during this period. While essentially the same type of fibroplastic inflammation characterized all the cases, this grouping brought to light certain important differences. In the early cases, the tissues were reddened, vascular, and edematous, and the tendon was dull, swollen, and discolored. In the later cases, the sheaths were thickened, fibrotic, and less vascular, the tendon was roughened and scarred and the acute inflammation was considerably diminished. Striking was the fact that in the

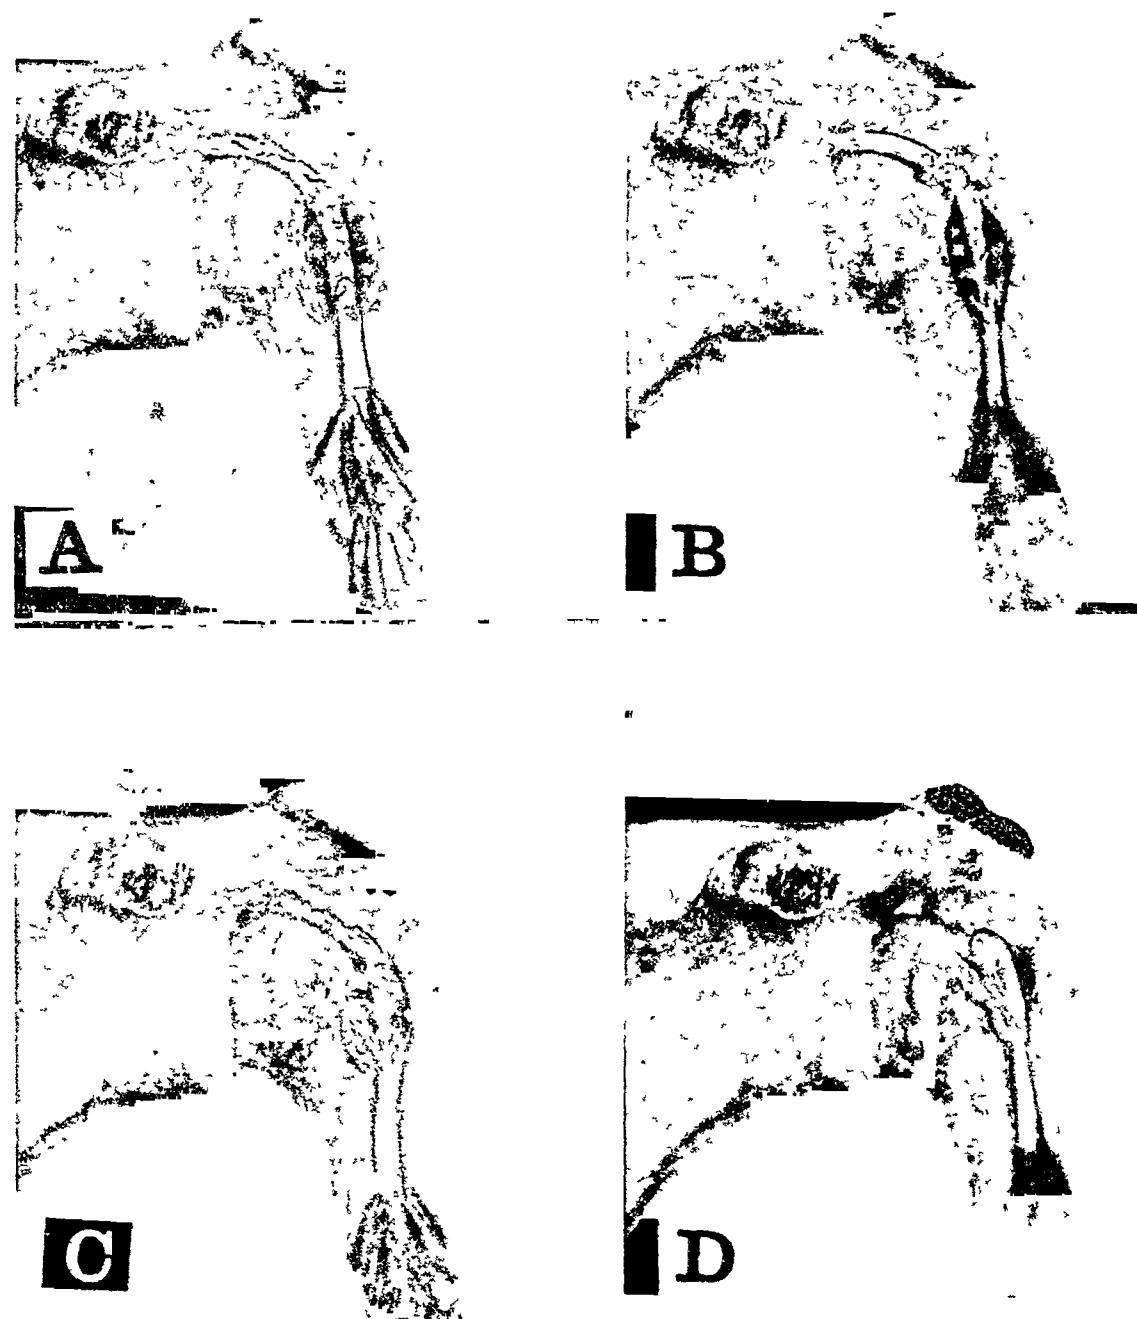

FIG 4 Pathologic sequence which appears to underlie most frozen shoulders as reconstructed from operative material.

B—Peritendinous adhesions forming. Inflammation commencing to subside.

C—Adhesions binding tendon to groove. Intra-articular tendon atrophic.

D—Cured. No inflammation. Biceps tendon firmly attached to lesser tuberosity. Intra-articular tendon disappeared.

early cases the tendon still was movable, whereas in the majority of the later cases it had become firmly bound down to the humerus with strong adhesions (Figs. 3 and 4).

#### Discussion

It is plain from these surgical studies that bicipital tenosynovitis is a pathologic change encountered with great frequency in frozen

shoulder. Can this lesion, then, be regarded as the underlying pathologic factor in the condition? The bicipital groove tenderness that characterizes all of these cases supports this contention, as does the fact that in the operating room all barrier to free shoulder motion generally vanishes as soon as the peritendinous adhesions are severed, although the exact mechanism of the block is still obscure. The easy access of the inflammation in the tendon sheath to the outer quadrant of the shoulder joint has been pointed out in the above anatomic considerations, and no doubt such extension does occur and may assist the tight tendon in binding down the shoulder. Is it possible that the reverse exists—that we are dealing with an inflammatory process primarily in the joint, with extension into the tendon sheath? Against this contention are the following facts: the joint itself is not tender and the clinical course is not that of a true arthritis. Moreover, in the operating room, release of the tendon immediately releases all shoulder restriction, indicating that no true contracture of the joint capsule is present. Finally, whatever intra-articular inflammation occurs appears to subside as soon as the tendon becomes fixed to the humerus.

The ultimate fusion of the tendon to the bicipital groove that has been observed in typical cases suggests an explanation for the spontaneous cure that characterizes this illness as well as for the clinical observation that, after a typical attack, recurrences never develop.

In this connection it is interesting to note that in 4 out of 150 anatomic shoulder dissections (2 $\frac{2}{3}$  per cent), Horvitz,<sup>2</sup> of Philadelphia, noted fusion of the biceps tendon to the lesser tuberosity with rupture of the intra-articular portion of the tendon.

### Therapy

The bicipital tenosynovitis that appears to underlie the frozen shoulder provides a sound basis for the evaluation of therapy. In conservative treatment, for example, brisement forced during the early part of the illness is obviously futile. Tearing of soft adhesions in the presence of marked inflammation serves only to cause more pain, and the adhesions promptly reform. This is in line with our clinical experience, which also supports the importance of rest, perhaps with palliative applications of heat or cold. Our experience with x-ray therapy in mild analgesic doses in over 30 cases was disappointing, with relief in only a small proportion of them.

In the latter part of the illness forcible manipulation under anesthesia occasionally produces startling results. The loud snaps audible during this procedure probably result from rupture of

the attenuated and functionless intra-articular tendon. In my experience, however, stretching of the arm at regular intervals with active exercise is more consistently helpful, less traumatic, and, in the light of the underlying pathology, appears more logical. A surgical method of treatment is also suggested by the pathological findings—namely, firm suture of the involved tendon to the adjoining lesser tuberosity. This procedure is easily accomplished through a small deltoid-splitting incision and it reproduces rapidly what occurs naturally so slowly and painfully. When the operation is performed during the early phase of frozen shoulder, while the tendon is still mobile, there is quite prompt relief from pain and improvement in shoulder motion follows rapidly and steadily. At the end of five or six weeks sufficient return has generally occurred to permit resumption of full activity. In considering surgical therapy, it is important to bear in mind the benign character of frozen shoulder. The most that surgery can accomplish is expedition. For this reason, I favor its employment only after careful exclusion of occult thoracic disease and then only when some clear-cut need for urgency can be presented by the patient. There are times when the saving of a few months of severe pain or invalidism appears well worth while and entirely justifiable. Results in such cases have been gratifying and will constitute the material of a separate report.

### Summary

The typical clinical aspects of periarthritis, or frozen shoulder, are reviewed, with emphasis on the fact that, though its duration is unpredictable, the condition almost invariably terminates spontaneously in complete recovery.

Surgical investigation on more than 30 cases of frozen shoulder has revealed that at least in most instances the subdeltoid bursa and underlying musculotendinous cuff are not involved and that, instead, tenosynovitis of the long biceps tendon and sheath is consistently encountered.

Adhesive tenosynovitis extends from the sheath into the outer quadrant of the shoulder joint proper, but the entire inflammatory process subsides spontaneously when the tendon becomes firmly attached to the bicipital groove and its motion is so obliterated.

The pathologic sequence underlying periarthritis provides a guide for the administration of conservative therapy and suggests a simple surgical approach when more rapid cure is desired.

## Discussion

Dr. Otto Steinbrocker, *New York City*—As an internist or rheumatologist I deem it a privilege to take part in this unusual surgical program. Our understanding of shoulder disability will be greatly increased by Dr. Lippmann's surgical investigations and by the extensive clinical studies of Drs. McLaughlin and Bosworth.

Dr. McLaughlin has made a remarkably clear analysis of the evolution and the status of treatment of calcific deposits at the shoulder. A comparative study of various methods of therapy has been a much-needed contribution in this field. The study of a control series greatly enhances the significance of his observations on treatment even if I cannot subscribe to all of his conclusions.

Calcific deposits at the shoulder may occur in systemic disturbances, as in generalized calcinosis, gout, hyperparathyroidism, scleroderma, and other conditions. They are usually asymptomatic, like the silent deposits frequently found in otherwise healthy people. Acute calcific disorders, as Dr. McLaughlin has emphasized, often clear up after a brief period of symptoms without requiring any interference. When the patient clamors for relief we employ aspiration or two-needle irrigation with procaine. Surgery undoubtedly provides the most effective approach for some acute and chronic calcific disorders of the shoulder. Dr. McLaughlin has well summarized the indications for operation in acute cases urgently needing relief.

So far I have seen one patient with chronic shoulder disability associated with calcification presenting immediate indications for surgery. He showed a dense, almost stony calcification. In some instances in which we have failed to get satisfactory results otherwise, we have recommended excision of the calcific deposits. We felt that the changes in these cases were not as simple as they looked in the x-ray films, and that exploration would reveal additional pathology. Some patients, however, at the onset or at any time in their course, will not submit to surgery, or are unfit for it.

For the past six years we have employed local and regional analgesia in shoulder disabilities. My remarks are based on approximately 200 chronic cases, the majority of which received diagnostic or therapeutic blocks. We depend upon local or regional analgesia to relieve pain and relax muscle spasm in order to permit gradual and tolerable mobilization of the extremity. Their chief value seems to lie in the assistive motion and gentle manipulation which are permitted to be applied immediately. In chronic disability associated with calcification mere needling or attempts at aspiration without procainization are unsatisfactory procedures. In fact, the symptoms may be aggravated for twenty-four to forty-eight hours. The injection of procaine is made through the point of maximum tenderness, usually over the site of calcification. Often additional points of severe tenderness can be elicited. These are injected too. The same procedure is employed in periarticular fibro-

sis with palpable tender points. We have found local puncture and infiltration of procaine effective in 50 to 60 per cent of the chronic cases.

At any tender area skin hyperesthesia, when unrecognized, may prove misleading by actually representing segmental referred symptoms or conversion symptoms. Routine palpation in such cases and injection of the tender site or the calcification usually prove ineffective. In chronic calcific or periarticular disorders not responding with appreciable relief of pain and/or some relaxation of muscle spasm after two local injections, and the other measures, we use brachial plexus block. This is a more reliable method than local infiltration. We reserve it for those patients who fail to respond after the simpler local procedures.

Each infiltration, local or regional, usually is followed by variable but definite relief of pain and increased passive or active mobility. We have employed these measures in control cases without other treatment and have found the rate of recovery better than in patients treated by other nonsurgical methods or in those carried without treatment. The patients are injected once or twice a week. The average requirement is six infiltrations, the most twelve. The use of procaine is, of course, only the means to our objective. Once mobility is well under way we depend only on exercises, assistive motion, and physiotherapy. Patients without disability are not injected unless palpable tenderness is found accompanying the pain and a correct response is elicited by saline infiltration. Recurrences have been few.

Dr. Lippmann's paper sheds new light on the subject of the "frozen shoulder." Periarticular fibrosis or periarthritis is diagnosed also in the majority of the shoulder disabilities at our clinic. He has conclusively accounted for many of these obscure cases. We will now make it routine to search for the signs he has described. The term "frozen shoulder," however, has been found by us to be rather misleading. It implies a chronicity and unresponsiveness rarely seen by us in the type of case admitted to the medical and arthritis services.

Many a disabled shoulder sent to us as "frozen," after a variety of therapy, began to thaw out with the first brachial plexus block or periarticular injection. In a recent series of 54 patients with chronic shoulder disability carefully studied for local point tenderness and emotional background, treatment abolished pain and restored 75 to 100 per cent function in 78 per cent of the patients, most of whom were discharged within eight weeks. When those patients with severe neurotic manifestations are excluded, the satisfactory results are further increased.

The symptoms of chronic periarthritis develop in some middle-aged or elderly individuals with hemiplegia, coronary arterial insufficiency, myocardial infarction, Parkinson's syndrome, and other inactivating conditions. Occasionally, a prolonged shoulder disability is due to conversion hysteria. Many mild or moderately "painful" and refractory stiff shoulders are of psychogenic origin. The history of an injury or the occurrence of a calcified

deposit in the x-ray film usually leads to the diagnosis of periartthritis or a calcific disability. We have found the presence of wide-spread skin

hyperesthesia, the response to consecutive infiltration of saline and procaine, and a detailed personal history invaluable clues to these cases.

## NEW YORK ACADEMY OF MEDICINE PRESENTS AFTERNOON LECTURES

The Friday Afternoon Lecture Series for 1944-1945 will be held at 4:30 o'clock at the New York Academy of Medicine. The program will be as follows:

November 3—"Recent Advances in Drug Therapy," by Dr. James A. Shannon, associate professor of medicine, New York University College of Medicine

November 10—"War Fractures," by Lt. Col. T. C. Thompson, (MC), AUS, Chief of Orthopaedic and Amputation Sections, Walter Reed General Hospital, Washington, D. C.

November 17—"Newer Concepts of Bronchial Asthma and Treatment," by Dr. Joseph Harkavy, associate physician, Mount Sinai Hospital

December 1—"The Problem of Infection in Burns," by Dr. Frank L. McLeney, associate professor of clinical surgery, College of Physicians and Surgeons, Columbia University

Dr. . . . . . Ab-

Dr. . . . . . and  
Course of Essential Hypertension," by Dr. Arthur M. Fishberg, associate physician, Mount Sinai Hospital

January 5—"The Therapy of Liver Diseases," by Dr. Charles L. Hoagland, physician, the Hospital of the Rockefeller Institute for Medical Research

January 12—"Present Trends in the Treatment of Pulmonary Tuberculosis," by Dr. H. McLeod Riggins, associate in medicine, College of Physicians and Surgeons, Columbia University

January 19—"The Modern Concept of Rheumatic Fever," by Dr. Robert F. Watson, the Hospital of the Rockefeller Institute for Medical Research

January 26—"The Problem of Alcoholism," by Dr. Howard W. Haggard, Director, Laboratory of Applied Physiology, Yale University

February 2—"The L. Duncan Bulkley Lecture: "Hormone Therapy and Human Mammary Cancer," by Dr. Fred W. Stewart, pathologist, Memorial Hospital

February 9—"Specific Remedies in the Prevention and Treatment of the Exanthemata," by Dr. Philip M. Stimson, physician, Willard Parker Hospital

February 16—"Shock Treatment of Psychoses," by Dr. Nolan D. C. Lewis, Director, New York State Psychiatric Institute

March 2—"The Hormonal Treatment of Prostatic Malignancy," by Dr. Clyde Leroy Deming, clinical professor of urology, Yale University School of Medicine

March 9—"Pathogenesis, Diagnosis, and Treatment of Anemia of the Newborn," by Dr. Peter Vogel, Adjunct Physician for Hematology, Mount Sinai Hospital

March 16—"Recent Advances in Laboratory Procedure," by Dr. N. Rosenthal, associate physician and hematologist, Mount Sinai Hospital

March . . . . .  
tion . . . . .  
Mar . . . . .

of the . . . . .  
case," b . . . . .  
of medic . . . . .

April 20—"Indications and Contraindications for Caudal Analgesia," by Dr. Clifford B. Lull, clinical professor of obstetrics, Jefferson Medical College

## DIRECTORY OF AFFILIATED CARDIAC CLINICS PUBLISHED

. . . . .  
. . . . .  
. . . . .  
. . . . .  
. . . . .

which have met the standard requirements of the New York Heart Association and of the New York Tuberculosis and Health Association. There are sixty-seven such clinics located in New York City, thirty-six in Manhattan, seven in the Bronx, seventeen in Brooklyn, and seven in Queens.

Listed in the *Directory* also are the vocational rehabilitation and employment services for cardiac patients in New York City, and the cardiac convalescent homes available to residents of this city.

These are: the convalescent Home of the Burke Foundation in White Plains, Irvington House at Irvington-on-Hudson, Pelham Home for Children at Pelham Manor, St. Francis Sanatorium for Cardiac Children in Roslyn, Long Island, and the Speedwell Society at 446 East 88th Street, New York City.

# TREATMENT OF POLIOMYELITIS

IRVING J. SANDS, M.D., Brooklyn

IN ORDER to discuss the treatment of poliomyelitis intelligently, it is opportune to review certain fundamental etiologic and pathologic facts regarding this disease. Poliomyelitis is an acute infectious disease that is caused by the invasion of the nervous system by a filtrable virus.<sup>1,2</sup> This virus is one of the smallest of the filtrable viruses that can be passed through the finest filters and membranes, that is resistant to phenol and ether, and that is most readily dissolved by oxidizing agents such as hydrogen peroxide and potassium permanganate and by ultraviolet rays, and by heating to a temperature of 55 C. for as short a time as five minutes. The virus has been found in human stools and in sewage.<sup>3</sup> This virus is highly neuronotropic in its tissue affinity.<sup>4</sup> Furthermore, it has been shown that there are apparently several types of poliomyelitis viruses, so that the serum of a monkey convalescent from one type will not protect the monkey against a different strain. This may account for second attacks of poliomyelitis.<sup>5</sup> Experiments have indicated that the most likely portal of entry in the human is the tonsillar-pharyngeal region, and also the gastrointestinal tract,<sup>4</sup> most probably by way of the mouth. The virus reaches the nervous system by the regional cranial or peripheral nerves. It travels along the axones, reaching the nerve cells proper. It is striking that as soon as it reaches the central nervous system it is localized in the motor cortex of the brain, the diencephalon, the mesencephalon, the medulla, the pons, and the spinal cord, the motor cells being the ones invariably involved.<sup>6</sup>

Poliomyelitis, therefore, is anatomically a meningoencephalomyelitis<sup>7</sup> with the motor nerve cells being primarily involved, and those of the anterior horn cells of the gray matter of the cord and of the cranial nerves of the pons and medulla bearing the brunt of the lesion. Not all of the nerve cells invaded by the virus are completely destroyed, and reversible changes may occur.<sup>6</sup> Since the pathologic process is confined to the central nervous system, the disease is primarily a neurologic disorder.

## Pathology

The brain is swollen and edematous and there is marked congestion of the pia, especially at the base, and particularly about the pons and medulla. The spinal cord is edematous and con-

gested and its vessels, particularly on the anterior surface, are swollen and engorged with blood. Section of the cord and the medulla will disclose marked hyperemia of the gray matter, especially of the anterior horns. Microscopic section discloses both mesodermic and ectodermic changes. The pia is edematous, congested, shows proliferation of the fibrous tissue, and is infiltrated with polymorphonuclear leukocytes, lymphocytes, and numerous red blood cells. The blood vessels show hyperplasia of their endothelial linings and will show infiltration of the Virchow-Robin lymphatic spaces with polymorphonuclear leukocytes, lymphocytes, and plasma cells. Small hemorrhagic areas are only rarely encountered. The ectodermic changes involve both the neurons and the neuroglia. The motor cells show cloudy swelling, chromatolysis, neuronophagia, and vacuole degeneration. In the early stage of the disease the nerve cells may show neuronophagia by polymorphonuclear leukocytes,<sup>6</sup> but after a few days the neuroglial element predominates. In a week or so, one may find areas in the anterior horns where there has occurred complete disappearance of nerve cells which have been replaced by polymorphonuclear leukocytes, lymphocytes, and microglial and neuroglial elements.

## Clinical Types

While the disease, anatomically, is a diffuse meningoencephalomyelitis with the myelitic and bulbar elements predominating, the clinical types present themselves in the following forms:

1. *Abortive Type*.—This is characterized by an acute and mild febrile disorder, occurring during epidemics, and showing no signs referable to involvement of the nervous system. A diagnosis is made only by implication.

2. *Meningeal Type*.—This is characterized essentially by signs of meningeal irritation, with rigidity of the neck, slight spinal tenderness, and rarely tremor.

3. *Bulbar Type*.—This type is characterized by symptoms referable to involvement of the seventh, ninth, tenth, and eleventh cranial nerves. The vestibular mechanism may also be involved in this particular type.

4. *Myelitic Type*.—This is characterized by paresis and paralysis of the skeletal and limb muscles, and of the diaphragm.

5. *Bulbomyelitic Type*.—This type is characterized by clinical signs referable to lesions

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

of the cranial as well as the peripheral motor nerves.

*G. Encephalitic Type.*—This is a rare form, generally complicates the bulbomyelitic type, and is characterized by extreme drowsiness, stupor, aphasia, sphincteric disturbances, and even convulsions.

A diagnosis is made on the history of the onset of the illness, the physical examination, and the spinal fluid study. The onset is generally sudden, with fever, headache, vomiting, and constipation associated with restlessness, irritability, and insomnia or, more commonly, somnolence. The patient appears apprehensive, anxious, and resents examination. The face is flushed, the pulse is rapid, and the patient appears prostrate. Nuchal rigidity and mild Kernig signs are generally present. The temperature is between 101 and 103 F., usually only about 102. The blood count is between 10,000 and 15,000 white blood cells, with a polymorphonuclear cell count of 45 to 60, there being an absolute and relative lymphocytosis. The fever may continue for three to five days and then subside. In the myelitic type there ensues, in a day or two after the onset of the illness, weakness or paralysis of muscles in the limbs, abdomen, thorax, or diaphragm. In the bulbar type<sup>8</sup> there is involvement of the cranial nerves, the seventh, ninth, tenth, and eleventh being the ones principally involved.

The bulbar<sup>8</sup> group may into two types include:

1. Unilateral, in which there is unilateral paralysis of the palate with congestion of the pharyngeal wall fauces and mucous membranes, lagging of one side of the palate, and a slight nasal twang to the voice, difficulty in swallowing for a day or two, and weakness in coughing. The fever in this group generally subsides in five to ten days and recovery usually ensues.

2. Bilateral, in which there is bilateral paralysis of the palate with increased nausea and salivation, uniform congestion of the oral cavity, collections of mucus behind the posterior pillars, labored respirations without supra- or infra-sternal restriction, nasal voice, indistinct articulation, marked difficulty in swallowing, especially of fluids, and with a very slow recovery and persistence of signs for many weeks.

If the temperature in these cases is down for forty-eight hours, no extension of paralysis has been observed. Involvement of the vasomotor center in this group invariably proves fatal. In the encephalitic form, the fever may persist for three or four weeks, ranging between 101 and 103 F., and then there is a gradual recovery; however, I have seen the temperature rise within three to four days after the onset of the illness, and death may occur within a few days.

The spinal fluid comes out under increased pressure, usually 150 to 250 mm. of water. The cell count varies from 50 to several hundred; in the myelitic form, usually from 50 to 200 cells, in the bulbar type from 50 to 75 cells, and in the meningeal type from 100 to 600 cells. It is my experience that the spinal fluid cytology within the first day or two after the onset of the illness is predominantly one of a polymorphonuclear increase; however, after the second day there is a relative lymphocytic increase. This follows very closely the type of cell encountered in experimental poliomyelitis.<sup>6</sup> At the onset of the illness, the total protein content in the spinal fluid is usually between 65 mg. per cent and 85 mg. per cent, generally averaging 75 mg. per cent, but it may be as low as 35 mg. per cent and as high as 120 mg. per cent. However, in the succeeding weeks, it rises gradually to about 250 mg. per cent and even to over 300 mg. per cent. It is always higher in the encephalitic types.

### Treatment

There are but few diseases that are accompanied by such universal anxiety and emotional tension as poliomyelitis.<sup>9</sup> There are few diseases in which so many contradictory forms of therapy have been advocated. For the past three years the therapy of poliomyelitis has been receiving increased attention because of the introduction of the so-called Kenny method of treatment.<sup>10</sup> When working with these patients she noticed there was an involuntary shortening of certain muscles of the body brought about by involuntary painful, spasmodic contractions. It was her opinion that this muscle was sick and needed nursing and it was her first objective to get rid of this painful condition and to allow relaxation to occur. After trying various means of alleviating these painful contractions, she finally arrived at the method of applying light woolen material wrung out of boiling water with a light protective material on top of that. She then noticed that the muscle, pulled out from its normal resting length, had forgotten how to contract and she therefore tried to convert the mind to the tendon of this "alienated muscle." She also observed that there occurred an interruption in the normal flow of impulses and that the impulses ran riot, as it were. "Thus were the symptoms—spasms, alienation, and incoordination—in this disease known as infantile paralysis, discovered thirty years ago" by her. Kenny regards muscle spasm as the most damaging symptom in poliomyelitis, and the muscles opposed to those in "spasm" become "alienated," or divorced from the patient's mind. In her conception, the "muscles in spasm" are the damaged ones. The Kenny treatment as well as her con-

ception of the pathologic process of the disease received a most unusually favorable response, not only from the lay public but from many of the leaders in the medical profession.<sup>11-13</sup> In certain medical quarters it was regarded as heresy to question her method of treatment or her explanation of the underlying pathologic and physiologic processes.

It soon became quite apparent that the Kenny conception of the pathology and dysfunction occurring in poliomyelitis was quite at variance with the usual orthodox understanding of the pathologic process of this disease. One observer spoke of Kenny's method "as the newest and the most popular fad."<sup>14</sup> Moldaver,<sup>15</sup> employing chronaxia and electromyographic studies, flatly controverted the Kenny findings, and he concluded as follows:

1. "'Muscle spasm' is not 'the most damaging symptom' and does not lead to neuromuscular degeneration. 'Spasm' is not an entity, but a complex phenomenon. It is the result of a combination of the normal stretch reflex, meningeal irritation of the posterior roots, increase of the normal tonus in healthy and strong muscles or muscular fibers opposed to weak or paralyzed muscles, lesions of dorsal root ganglions and posterior horns. Pain is a common symptom in acute poliomyelitis. This is a referred pain which is increased by stretching of the muscles.

2. "In 'alienated muscles' there is neither a functional paralysis nor a 'physiologic block.' That these muscles have partially or completely lost their power to contract is due to the fact that the anterior horn cells are damaged or destroyed. In the paralytic or paretic muscles considered to be 'alienated,' there is always some degree of neuromuscular degeneration.

3. "'Incoordination' does not consist in a misdirection of nerve impulses. It is caused, if at all, by the inability of partially or totally denervated muscles to respond to otherwise normal nerve impulses."

Watkins, Brazier, and Schwab,<sup>16</sup> as a result of their electromyographic studies, likewise disagreed with the Kenny concept of the pathologic process in poliomyelitis. They summarized their findings as follows:

1. "In poliomyelitis the term 'muscle spasm' is inadequate to describe the complexity of dysfunction which is revealed by electromyography.

2. "In the acute stage, only muscles with some degree of paralysis discharge electric potentials at rest; these electric abnormalities are not correlated with the presence of clinical 'spasm.'

3. "Partially paralyzed muscles are hyperirritable to passive stretching, as indicated by electric discharges and pain; the muscle tension thus developed appears to be a reflex protective mechanism.

4. "The electric activity in paretic muscles at rest increases during the period of improving motor power, and the pattern of discharges corresponds with that seen in muscles during regeneration of peripheral nerves. When improvement in motor power ceases, spontaneous electric discharges disappear.

5. "No abnormal electric activity is associated with the muscle contractures of the late stage of poliomyelitis, nor are any discharges present in completely paralyzed muscles.

6. "The concept of 'mental alienation' does not contribute to the explanation of paresis in our cases, since objective signs of a disease process were always present in the paretic antagonists of muscles in 'spasm.'

7. "Increase of voltage of action potentials during successive ergographic tests is an index of recovery of motor power.

8. "Of the three concepts of Kenny, the only one upheld by our objective measurements is that of 'incoordination,' although the term is misleading. We demonstrated not only simultaneous activation of protagonists and antagonists but also intermittent synchrony of individual discharges from opposing muscles, such as is found in peripheral nerve injuries during regeneration of axons. Disordered reciprocal innervation seems to be a more descriptive term for this type of dysfunction."

Commenting upon the situation, Cobb<sup>17</sup> said: "Thus it is being demonstrated once more in the history of medicine that new and empiric methods of treatment, backed by uncritical enthusiasm, may produce many cures but much physiologic nonsense. The treatment may be good but the ex post facto rationalizations of the therapist are usually bad."

Since 1916 I have had the opportunity of observing poliomyelitis patients in various neurologic centers, general hospitals, and, for the past fifteen years, at the Kingston Avenue Hospital for Contagious Diseases, which serves a population of approximately three million people. I have performed autopsies on several patients who have died from this disorder. I have observed the different forms of therapy applied during a period of over a quarter of a century. I have attended a clinic held by Sister Kenny, and I have also witnessed the demonstration of the application of the treatment at the 1942 convention of the American Medical Association in Atlantic City. I have observed and followed the "Kenny Treatment" as given in the Kingston Avenue Hospital for the past eighteen months. It is readily acknowledged that Sister Kenny is an excellent physiotherapist who has profound knowledge of the functions of muscles, and who is a persevering worker. I have become convinced that the application of fomentations as prescribed by her relieves pain and makes the patient comfortable. Credit is due to her for stimulating

the medical profession to the institution of active treatment in the acute phase of the illness.

Poliomyelitis is a disease that attacks primarily the motor apparatus of the nervous system, especially the anterior horn cells of the gray matter of the spinal cord, but lesions are also found in the posterior horns, in the sympathetic column, and in the dorsal root ganglia. The motor cerebral cortex, the thalamus, the pons and medulla, and the cerebellar nuclei are also involved. Some cells are completely destroyed, others are partially damaged and in some the process is indeed a reversible one. In the early stage of the disease there is marked meningeal irritation, and this, plus the involvement of the dorsal root ganglia, the posterior roots, and posterior horns, accounts for the pain that is so prevalent in the early stage of the disease. The paralysis is a flaccid one. Tenderness on pressure of the muscles and pain caused by active and passive motion of the limbs are common findings. Baking, massage, muscle training, and some form of immobilization seemed to have been the therapy a quarter of a century ago.<sup>18</sup> Some advocated keeping the children in bed at least one year, others for a still longer period of time. Some advocated immediate treatment, particularly application of heat in the acute phase. Warm water pools and electric therapy were advocated by others. I agree with McCarroll,<sup>14</sup> who said: "Our knowledge of the pathology of poliomyelitis, long recognized and often proved, should not permit us to accept and sanction unquestionably any treatment which in reality amounts to nothing more than tinkering with the peripheral secondary change in the muscles themselves."

The treatment of poliomyelitis is purely symptomatic and palliative. The patient should be removed to a hospital equipped for the treatment of poliomyelitis cases. The vast majority of the patients, particularly those who have only the meningeal form, will get well at the end of two or three weeks without any particular form of therapy and without any residual effects. However, there are certain specific symptoms that require actual and symptomatic care. The relief of pain is best accomplished by artificial heat. It matters very little whether it is given in the form of a cradle lined with tungsten lights (infrared) as advocated by Toomey<sup>19</sup> or by hot fomentations as taught by Kenny. The fact of the matter is that the patients feel more comfortable and lose a good deal of their anxiety when heat is applied. The bowels require care. A saline cathartic such as 2 oz. of a 50 per cent solution of magnesium sulfate daily for the first two days and a daily soap-suds enema will be desirable. The saline cathartic has the additional benefit

of reducing edema of the central nervous system. Occasionally abdominal distress is caused by gas being pocketed in the intestines that have become segmentally parietic. A rectal tube or a soap-suds enema frequently relieves that pain. Paralysis of the bladder is not common. It may be encountered in those patients in whom there is involvement of the lumbosacral segment of the cord or of the autonomic nervous system with weakness of the detrusor urinary muscle and of the internal sphincter muscle. Catheterization may have to be employed, and caution should be taken to prevent infection of the bladder. The restriction of fluid to approximately 1,500 cc. in twenty-four hours has been accepted as a universal procedure. The diet should be soft and semisolid for the first few days, but of adequate caloric and vitamin content. When one considers the disease process in the light of the underlying pathologic and anatomic changes, it becomes apparent that some of the muscle weakness which clears up even without any treatment is due to the edema of the cord and the rest of the nervous system. Hence, 50 cc. of a 50 per cent solution of glucose should be given twice daily for the first three or four days of the acute phase of the illness.

Regarding the care of the muscles that are parietic or even paralyzed, the following facts must be taken into consideration. The disease is of the nervous system, and not of the muscle itself. The changes in some of the nerve cells are reversible, in others they are permanent and lead to the death of the cells. If a muscle or a group of muscles is deprived of all of the nerve cells supplying it, these muscles are bound to atrophy, regardless of whatever method of therapy is applied. However, in the majority of instances, even in the most serious cases, there are some nerve cells left and it is for this reason that subsequent physiotherapy may result in functional recovery of many parietic and even paralyzed muscles. Twenty-five years ago Feiss<sup>20</sup> advocated early active treatment of poliomyelitis. He took a strong stand against the recommendation of the Harvard Infantile Paralysis Commission,<sup>21</sup> which recommended prolonged rest and fixation. He insisted the passive and active movements of the muscles should be instituted even in the acute phase of the illness. Such procedure has given good results in the hands of many. Stiffness of the antagonistic nonparalyzed muscles is due to the hypertonicity resulting from factors mentioned in the early part of the paper. Hence, gentle massage and manipulation of the limbs are helpful not only for the paralyzed but also for the antagonistic normal muscles. Sandbags, splints, and even braces must be used to prevent stretching of the par-

alyzed or paretic muscles. When the acute phase is over, persistent passive and active motion, electrotherapy, underwater exercises, and calisthenics should be employed and should be kept up until the muscle has resumed nearly as normal a function as it had prior to the onset of the illness. It is to Kenny's credit that she has once again aroused the interest of doctors in intelligent physiotherapy. However, let me re-emphasize that there is nothing in her methods and procedure, except for finer points, that has not been employed by physicians as far back as the 1916 epidemic. Moreover, no one has a monopoly on the intelligent application of physiotherapy. I have met several intelligent and well-trained physiotherapists right in our own country and in our own city, who have worked quietly and efficiently and persevered until they have restored the paralyzed poliomyelitic limbs to nearly as normal a state as could possibly be expected in the light of the underlying pathologic process.

Flail-like muscles are not now encountered as commonly as they were a quarter of a century ago. When this condition occurs, it is the result of destruction of all the anterior horn cells supplying all the muscles to these limbs. Even in these cases, if early and persevering treatment is instituted, improvement may ensue. It must be remembered that all active and passive movements should not go beyond the point of fatigue.

The question of serum therapy is not, as yet, a settled one. It may no longer be said that if a virus invades the nerve cell the cell will invariably die. It has been pointed out that many of the nerve changes are reversible ones.<sup>6</sup> Furthermore, it sometimes takes as long as three to four days before paralysis ensues. Toomey<sup>22</sup> claims that the disease can be prevented in animals protected with convalescent serum when the disease is given via the gastrointestinal tract. In the human being the virus probably enters through the mouth and gastrointestinal tract and it takes time for it to reach the nerve cells proper. Hence, the problem of neutralization of the virus by employing convalescent blood serum<sup>23</sup> or even transfusions<sup>24</sup> should be once again opened up and given a real scientific trial.

The bulbar type of poliomyelitis<sup>8</sup> requires special skill in its management. The patient should be put in the prone position upon a hard mattress and the foot of the bed elevated to insure drainage. The accumulation of mucus in the back of the throat should be removed by swabbing, or preferably by suction. It is imperative that these patients receive fluids either by rectum, by vein, or by hypodermoclysis. Hypertonic glucose, intravenously, serves the double purpose of furnishing nourishment and fluids and reducing edema. Nasal gavage should

not be begun till the temperature has subsided, and then only in small amounts, to obviate vomiting.

Respiratory disturbance is the most serious complication that is encountered in this disease. It may be due to (1) collection of mucus in the back of the throat caused by pharyngeal paralysis; (2) paralysis of the respiratory nucleus in the medulla; and (3) paralysis of the diaphragm and the intercostal muscles. When respiratory difficulty ensues, the child becomes markedly apprehensive, is very restless, and tosses about in bed, throwing his limbs about in a haphazard manner. He shows a peculiar, hacking, respiratory grunt, and tugs at the muscles of the front of the throat. He jerks his head about violently. There is dilatation of the alae nasi. There may be slight cyanosis of the lips and face.

The respirator should be used for patients who show diaphragmatic or intercostal muscle paralysis. It should not be used when respiratory embarrassment is caused by involvement of the medulla.

In the acute stage of the illness there are very few drugs that have any real value. Physiotherapy itself allays the anxiety and mental apprehension. Saline cathartics are necessary. It seems to me that the use of Vitamin E and Vitamin B complex in the acute phases of the disease may be well worth trying, for these drugs have a direct and specific action upon the nervous system. Those<sup>25</sup> who have used it believe that they have found it very helpful. After the acute phase is over, persistent physiotherapy in the nature of massage, passive and active movements, electrotherapy, particularly interrupted galvanic and sinusoidal current, and re-education should be employed for months and years until the paretic or paralyzed muscle has regained its fullest possible functional capacity. After this, orthopaedic appliances and surgical measures employed by a competent orthopaedist will help many to regain some functional usefulness of the paralyzed limbs. In the acute phase of the encephalitic form, forced spinal-fluid drainage should be employed.

### Prophylaxis

A word about prophylactic measures may not be amiss at this moment. A decade ago, a wave of nose-spraying of thousands of children with chemical agents such as zinc sulfate and picric acid followed the discovery that these substances had prevented nasal infections in one type of monkey. However, its failure to protect human beings is explained by the fact that the olfactory pathway is not the one by which the virus enters humans. Vaccinations<sup>26</sup> and injections of convalescent serum likewise proved disappointing.

General hygienic measures were also found wanting, because poliomyelitis attacks the most healthy and the most virile people. Nevertheless, there are many who still maintain that injections of convalescent serum<sup>22, 24</sup> may be used during epidemics as a possible preventive agent. Recently Sabin,<sup>27</sup> in his Béla Schick Lecture, has cast a ray of hope by calling attention to the following facts, namely, the presence of the virus in human stools, in sewage, and in flies which have been trapped in epidemic areas. Furthermore, the disease occurs during the summer months. He, therefore, pointed to the likelihood of the virus' being carried by flies through food to human beings. Possibly public health measures to eliminate the menace of flies may be the solution to the problem of prevention of poliomyelitis. Rigid quarantine, closing of schools or of summer camps in which cases of poliomyelitis have occurred, and delayed opening of schools during epidemics, are measures that should be condemned, for they are not based upon scientific facts and tend only to create panic.

### Summary

1 Poliomyelitis is a disease caused by a specific virus which enters the human being through the mouth and the alimentary canal. The virus is found in the central nervous system, in the walls of the alimentary canal, in stools, and in sewage.

2 The virus travels along the axones and edges in the motor cortex of the brain, the diencephalon, the mesencephalon, the medulla, and the anterior horn cells of the spinal cord. The cells of the motor apparatus are the ones that are involved in the pathologic process. Poliomyelitis is, therefore, a neurologic disease.

3 Clinical poliomyelitis may be classified according to the predominant signs into (1) abortive type, (2) meningeal type, (3) myelitic type, (4) bulbar type, (5) bulbomyelitic type, and (6) encephalitic type.

4 The treatment of poliomyelitis is symptomatic and palliative, heat, gentle massage, and early passive manipulations should be employed even in the acute phase of the illness. Convalescent serum is still useful.

5 Persistent physiotherapy for months and years must be employed to overcome paralysis that may follow.

6 Possible effective prophylactic measures are discussed.

# PROBLEMS IN THE POSTOPERATIVE CARE OF CANCER PATIENTS

NORMAN TREVES, M.D., F.A.C.S., New York City

A CHRONIC disease as widely prevalent as cancer and in which about 75 per cent of the patients die within four years of the time a diagnosis is made presents an enormous problem in terminal care. Pertinent questions with regard to terminal care are: What constitutes adequate care? What patients require hospitalization during this period? What facilities are available? Outside of New York City only about 35 per cent of the cancer deaths occur in institutions. Altogether, about 2.5 per cent of the total admissions to general hospitals are for malignant disease. Cancer, however, is a much more serious factor in the nation's health than this percentage indicates. The present development of special cancer facilities has not yet influenced favorably either the morbidity or the mortality from this disease.

The tabulation of cancer mortality in New York State during 1943, as prepared by the Department of Health,<sup>1</sup> listed cancer deaths of all forms to be 22,400. In 1942 the annual prevalence rate was 579 cases per 100,000 population. This is 3.6 times the mortality rate, according to Levin.<sup>2</sup> He likewise recalls that usually an estimate of cancer prevalence is based on a ratio of 3 cases per death and that, because of the incompleteness of morbidity reporting, these figures for New York State indicate too low a ratio. The prevalence may be four or five times as great as the mortality.<sup>3</sup> Taking the latter as a more likely figure, this would mean that there are about 112,000 persons with diagnosed cancer in the State. Depending on the site of the cancer, perhaps 30 per cent are free of disease. What about the remainder—78,400? This number represents a large group requiring specialized medical attention either in institutions or in the home. The facilities in this State for the institutional care of patients in the terminal stages of the disease appear inadequate. Their problems are, therefore, the problem of the practitioner who ministers to them in their homes.

More unpleasant than telling the patient or his family that cancer exists is the duty of informing the relatives that the disease has reached an unfavorable or even incurable stage. This is often the delicate duty of the general practitioner. He has had the patient returned to him following treatment by surgery or radiation therapy, and it becomes his unhappy task to discover recurrence

or metastases. It is then his job to take over from the specialist. It is to this group, the family physicians, that these remarks on the care of the patient with terminal cancer are addressed.

In approaching the problem of caring for patients with incurable cancer, we have to deal with a disturbed mental state. Two important questions arise—one is whether a patient should be told he has cancer, and the other is the question of ultimate prognosis. It seems certain that it is better for the physician to avoid telling the patient the nature of his disease—especially never to be the first to use the word "cancer," which has so many sinister connotations in the lay mind. The question: "Is it cancer?" is sure to be asked by the patient or his family or friends and many patients who will ask to be told the worst are least fitted to know it.

Regarding the second question: When a patient knows he has cancer, it seems most desirable to hold out the hope of recovery even to the last. The difference in the mental outlook of a man who believes his condition to be absolutely hopeless from that of a patient who believes that he has even a 1-in-1,000 chance of recovery is enormous. Even against such hopeless odds one may most infrequently expect spontaneous regression and even disappearance of an advanced cancer. It is quite possible that such regression has made the reputation of certain "constitutional" cancer cures.

But in all cases where there is no doubt as to the diagnosis, a doctor, for the sake of his own reputation, should tell some relative or friend of the patient what the nature of the disease is.

In all cases the close cooperation of the specialist with the general practitioner is indicated, not only in the active treatment of the patient, but where cure has not resulted. If the specialist and the family physician keep each other advised, each will accomplish his part of the work to the better advantage of the patient and the family. Wherever the patient is located during the terminal stages, his last days may be made much more comfortable by both intelligent care and medication as well as by optimistic psychotherapy. Never tell a patient suffering from cancer, or his friends, that there is nothing to be done; so long as life lasts there is help to be given, and there are few forms of the disease in which the doctor can earn more gratitude than he can by his management of a case of inoperable cancer.

Many physicians feel that the easiest way to treat the incurable cancer patient is to administer large doses of hypnotics or narcotics, and this is

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944.

Associate Surgeon, Memorial Hospital, and Director, Tumor Clinic, Meadowbrook Hospital.

often done indiscriminately. They reason that the end is inevitable and that if the patient is kept continuously under the effect of a drug, he is comfortable and the anxiety of his relatives is relieved. Since no one can tell how long the terminal phase of the disease will last, this attitude is deplorable. Even with the cautious administration of opiates, increased dosage often has to be resorted to so that huge amounts must be used. Neither a patient nor his relatives should judge the quantity of a drug, nor the time interval which should elapse between doses.

### Euthanasia

It has been felt by many members of the profession that once the terminal stage of cancer has been reached narcotics in large doses should be indiscriminately administered. But, since the life of the incurable cancer patient is usually of long duration, sedatives, hypnotics, and analgesics should be used with utmost caution.

"Euthanasia" literally means a gentle death of little suffering. Since the subject is not taught in any of our medical schools, the physician enters practice having to learn for himself what to do and what not to do in the most solemn and delicate position in which he can be placed—in attendance on the dying. It is for him to administer the resources of the medical art in aid of an easy, gentle, and placid death.

The word "euthanasia" refers to two things: first, the practice of painlessly putting to death those suffering from distressing symptoms as an act of mercy, and, second, the practice of relieving suffering so that the going-out of life may take place with as little distress and pain as possible. These are such totally different aspects that each should be considered separately.

The State has never sanctioned the first, and the physician is not given the right by any diploma he possesses to administer a drug to cause death. It is probable that even if it were permitted the majority of doctors would refuse to carry it out, since they enter their profession to maintain and prolong life, and not to take it.

Euthanasia is a matter of interest to all, for death sometimes comes very slowly, and delay may be tragic to the patient and those around him. A physician is permitted to give drugs to relieve pain and suffering so that life may go on with as little disturbance as possible and death may take place briefly. He may give as much medicine as he thinks a particular patient needs, provided the aim is to relieve symptoms. He must be guided by what is in the interest of the patient. It must not be assumed that the administration of drugs to relieve suffering necessarily hastens the end, for if the pain persists it will soon undermine the health, and even if a

drug has a depressing action, its harmfulness may be more than counterbalanced by the serious effect of the prolonged suffering and pain which it is given to relieve. Up to the present the State has entrusted to the medical profession a

laws that limit their power.

Good nursing and the due administration of light food and stimulants comprise all that is needed. The approaches to death are so gentle and the act of dying so easy that Nature herself provides a perfect euthanasia.

### Nursing Care

Sympathetic, efficient nursing care, when possible, is a great factor in caring for patients with incurable cancer. A cheerful attendant may be of inestimable value at this stage of the disease. The meticulous care of the patient, judicious medication, and frequent, gentle surgical dressings, when necessary, are not only prerequisites for comfort but may prevent the isolation of the individual. Friends and relatives are reluctant to remain in the room when the patient is uncomfortable or there is a noticeable odor, caused by either poor personal hygiene or the discharge from affected areas.

Frequent dressings diminish secondary infection and lessen the absorption of tumor toxins. These toxic products, when absorbed, add to the anemia usually present during the terminal stage of cancer. A nurse can arrange more comfortable positions for the patient, not only helping to make conditions more bearable but preventing the development of pressure sores. Cachexia may be obviated by carefully selecting the diet and giving frequent, easily assimilated nourishment with the addition of suitable vitamins.

### Chemotherapy

Mention should be made of certain clinical experiments which have been made in testing the use of heptylaldehyde bisulfite (sodium alpha-hydroxy heptane sulfonate) for the treatment of metastatic mammary cancer to bone. At the Memorial Hospital, under the direction of Rhoads,<sup>4</sup> and with the cooperation of the Breast Department, the work of Strong<sup>5</sup> on laboratory animals has been tested on humans. Those patients with definite roentgenographic evidence of disease who have elevated blood calcium and phosphatase levels have been treated. Eleven patients received a daily oral dose of the drug varying from 1 to 12 Gm. for from twenty to twenty three days. Three patients received the compound by continuous intravenous drip, a dose of 0.50 Gm. per Kg. of body weight per day. The

two modes of administration did not alter the expected course of the disease. Nor did any clinical regression parallel the laboratory experiments.

It has been reported that several types of cancers contain abnormally high amounts of biotin.<sup>6</sup> It has also been noted that the addition of biotin to diets which prevented in rats the development of hepatomas induced by feeding butter yellow<sup>7</sup> broke down the protection these diets afforded. These findings do not necessarily imply that biotin is required for the initiation or growth of a neoplasm, but may suggest that if biotin is withheld from cancer patients their neoplasms might be decreased. The existence in egg-white of a protein, avidin, which forms a complex with biotin has been known for several years. Administering it orally to rats induces a deficiency by preventing an absorption of biotin from the gastrointestinal tract. For these reasons Rhoads and Abels<sup>8</sup> fed two patients with malignant lesions for thirty weeks with sixteen to forty times the amounts of avidin necessary to bind *in vitro* the limited amounts of biotin in their diets. There was no evidence that a biotin deficiency had been induced nor were the amounts of biotin excreted in their urine abnormally low. Likewise, the clinical course of these patients was in no way

changed. It is our opinion that to date there is no conclusive agent which has been advised for the treatment of cancer inoperable cancer that is of intrinsic value. completeness of morb.

New York State issues

prevalence may be often does exist in conjunction with the mortality.<sup>9</sup> Taking these disorders. Heart and kidney disease, syphilis, and tuberculosis figure, this would mean that 112,000 persons with cancer as adequately, if not more so. Depending on the cancer as at any other time. Perhaps 30 per cent are free from immediate problems incident to the disease. Therapeutic measures that require a large group require the patient's attention either in institution or should be resorted to. The facilities in this State as to the relative value of care of patients in the hospital and intravenous drugs for ease appear inadequate reserve and stimulating apparatus. Therefore, the problem. There are numerous types of ministers to them in institutions that are satisfactory for oral

employed. While many of the measures resorted to may from the outset be doomed to failure, nevertheless the patient is encouraged psychologically if these are carried out. Whether the benefit is physical or mental, any results obtained would justify the means.

While it may be premature to accept in entirety the claims made for the administration of vitamins, we have been impressed with the favorable results. In treating patients with incurable cancer, vitamin B complex, vitamins B<sub>1</sub>, and C seem to have a definite sphere for their administration, as well as vitamins A and D. The diets of these patients are vitamin-deficient because: (1) the amount of food taken is small; (2) the diet is frequently liquid in character; and (3) the diet lacks balance.

Special modified diets should be outlined, the nature and location of the cancer determining the form. Patients with intraoral lesions require liquid or soft diets, permitting easier deglutition. The caloric content should be as high as possible because the pain caused by swallowing may limit the amount of food intake. The patient may increase his diet if, shortly before mealtime, the mouth and throat are sprayed with a weak cocaine solution. To avoid the use of cocaine, metycaine tablets of 1/2 grain each may be dissolved on the tongue. This local anesthetic has been found useful for this purpose and for diminishing the pain in ulcerating oral lesions. Euphagin and Nuporal lozenges are likewise of similar use.

Patients with carcinoma of the esophagus with gastrostomy must be maintained on a high-caloric liquid diet. Cooked cereals diluted with cream, to which large amounts of carbohydrates, preferably lactose, are added, may be given with little difficulty. Milk, with the addition of glucose or lactose, powdered milk, eggs, and creamed soups may be given. One should attempt to give a diet which will approximate 3,000 to 4,000 calories. Twelve ounces of the following formula given in six feedings will give approximately 3,000 calories:

1 teaspoon salt	1/2 cup lactose dissolved in
5 eggs	1/2 cup water
1 1/2 quarts milk	4 oz. strained spinach,
1 cup Klim	peas, or carrots
1/2 cup Karo	1 oz. salad oil

To this may be added:

4 oz. orange juice twice a day
3 drops vitamin A-D concentrate
3 teaspoons liver powder
1 tablespoon brewers' yeast

This mixture is not particularly palatable, but offers a concentrated diet, ample in calories, minerals, and vitamins. It may be used for nasal

feedings in intraoral cancer as well as for gastrostomy or jejunostomy administration.

When disease does not involve the gastrointestinal tract, a full maintenance diet should be given.

### Treatment of Nausea and Vomiting

Nausea, regurgitation, and vomiting may result from excessive nasal secretion, cough, headache, metastases to the skull or brain, gastritis, gastric or intestinal obstruction, or the absorption of toxins due to the breaking down of tumor tissue. It is evident that if certain of the organic conditions producing these symptoms cannot be eliminated, no amount of therapy will avail. However, proper elimination from the gastrointestinal tract, the insertion of a nasal tube, the frequent removal of excessive nasopharyngeal secretions, and the cleansing of necrotic wounds will always help the patient. Besides, a faulty diet, with low vitamin content, may produce these symptoms. If marked inanition is present, vitamins B<sub>1</sub> and C and liver concentrate should be administered hypodermically in full doses.

Absolute gastric rest is the single most important means of lessening the stream of afferent stimuli affecting the vomiting center. Rest should be obtained in a horizontal position or with the feet slightly elevated above the level of the head. The mouth should be kept moist. Fluids should be administered by other channels. An antiketogenic regimen should be instituted. A very useful formula which I have used and found of value is cerium oxalate, a 10-grain powder is given with 10 minims of dilute hydrochloric acid (through a drinking tube) as often as every four hours, if necessary. Teaspoonful doses of very hot or very cold or carbonated water, ginger ale, or champagne may be given every fifteen minutes. Brandy over cracked ice may be given and may prove useful when everything else has failed.

No matter how the vomiting originates, acidosis induced by the starvation it produces irritates the vomiting center in the medulla and maintains a tendency to nausea and vomiting even if the original cause has subsided. Here carbohydrate administration by intravenous drip is the chief remedy, even in the vomiting of the diabetic, in whom the carbohydrate administered should be "covered" by insulin. Alkalis are important in the presence of acidosis if much base has been lost.

### Care of Cutaneous Ulceration

The care of cutaneous ulcerations resulting from pathologic invasion of the skin by neoplastic extension, decubitus or the result of prolonged and intensive radiation therapy will often test the

resourcefulness of the practitioner. Certain medicaments may prove satisfactory for a time and then may seem to lose their efficacy. Besides, ulceration may be better controlled or healing may at times be affected if the formulas are changed frequently.

Ulcerating lesions should receive frequent, meticulous, surgical toilets, with neutral soap or any of the commercial naphtha soaps. Secondary infection plays a great role in increasing the local and general distress. When pain persists in spite of rigid antisepsis, additional measures must be undertaken for relief. Moist dressings of boric acid or potassium permanganate or azochloramid may be applied. Ointments are not as satisfactory, for they tend to seal in infection and prevent proper drainage. However, certain salves containing local anesthetics may be used.

One of the modes of treatment of skin ulceration, especially in the presence of macrobic bacteria, is the use of zinc peroxide. One must be certain that the preparation is active. The solution liberates oxygen for many hours and is an effective seal in preventing evaporation and drying.

Ulcers caused by irradiation effects on the body surface or pyogenic invasion when chronic, require the trial of many preparations to effect healing. Cod liver oil, high in vitamins A and D, is incorporated in an ointment base. The effect of applying such a salve is striking in the rapidity with which healing ensues.

Another preparation for the treatment of ulcers is Allantoin. It is a crystalline substance which stimulates healthy granulations and produces a medium apparently unfavorable to bacterial growth. Allantoin is used in 0.4 per cent aqueous solution on gauze.

A word of caution should be expressed concerning the use of sulfonamides incorporated in an ointment base. They may be applied to an uncomplicated skin ulceration. When radiation therapy has been employed and severe cutaneous reaction ensues, or when disease appears in an irradiated area, the sulfonamide seems to act as an irritant.

The skin often becomes ulcerated or macerated from the discharge of fungating cancers or fistulas from viscera. While zinc oxide ointment or linolin has been used in the past, we find an ointment containing powdered aluminum to be most efficacious. Its use is enthusiastically recommended.

### Physical and Therapeutic Castration to Control Inoperable Cancer

*Surgery Mammary Cancer*—More than fifty years ago Beatson observed that the rate of growth of mammary cancer might be inhibited

by oophorectomy. Dresser,<sup>9</sup> in 1936, reported on the effect of x-ray castration on the metastases to bone from carcinoma of the breast, feeling that the procedure was of value in patients who were still menstruating. Taylor<sup>10</sup> agrees with Dresser that in about one third of the patients with recurrent or inoperable cancer artificial menopause produces temporary regression or improvement. A further study of this problem has been under investigation at the Memorial Hospital and will be reported in the near future.<sup>11</sup>

*Surgery: Prostatic Cancer.*—Toward the close of the last century White and Cabot advised castration to reduce the size of benign hypertrophied prostates. Huggins,<sup>12</sup> considering these papers for the treatment of the same condition, again called attention to the subject but went further to apply it to advanced inoperable and metastatic prostatic cancer. Suffice it to say now that surgical castration seems to be a well-planned, acceptable, and relatively minor surgical procedure for the relief of incurable prostatic cancer. The effect seems to be fairly regularly obtained—diminishing the pain, reducing the size of the metastatic deposits, and improving weight and appetite. Huggins believes surgical castration to be of greater and more prolonged benefit than endocrine castration.

*Endocrine Therapy: Metastatic Mammary Cancer in Bone.*—The influence of androgenic substances on the serum calcium of skeletal metastases from mammary cancer has been studied by Farrow and Woodard.<sup>13</sup> In three cases of carcinoma of the breast metastatic to bone, injections of testosterone propionate were followed by a decided rise in the concentration of calcium in the serum and in the excretion of calcium in the urine. The chemical changes were accompanied by clinical and x-ray evidence of increased activity of the metastatic disease in the bones. In two cases of carcinoma of the breast without skeletal metastases, injections of testosterone, estrone, or progesterone were not followed by significant changes in the serum calcium levels.

The ability of testosterone and estrone to cause hypercalcemia in patients with carcinoma of the breast metastatic to bone appears to be caused by a stimulation by these hormones of the growth of the metastatic tumor. This in turn causes acceleration in the rate of bone destruction, accompanied by a flooding of the circulation by the products of osteolysis. The evidence demonstrated here that testosterone in large doses exerts a stimulating rather than an inhibiting effect on the growth of metastatic mammary carcinoma obviously contraindicates its use in this disease. The reason why an androgenic substance stimulates a tumor of a female reproductive organ remains obscure and merits further study.

*Endocrine Therapy: Metastatic Prostatic Cancer of Bone.*—It is believed that the results following the administration of stilbestrol are equal to, if not better than those following orchiectomy. But not all clinics are unanimous on the results. Huggins prefers surgical castration; Kearns<sup>14</sup> and Dean and his associates<sup>15</sup> feel that chemical castration is equally effective, thereby precluding surgical procedure. Kearns, in a recent report, noted that most surgical castrates suffered from mental depression, vasomotor disturbances, and lassitude; that there were unfavorable psychic and neurologic effects. Further argument for the use of estrogens was the observation of other investigators that since castration does not bring about complete cessation of androgenic activity, this procedure in some instances proves inadequate or ineffective and estrogen therapy must be resorted to. Kearns advises beginning treatment with 1 mg. of diethyl stilbestrol orally three times a day. This dosage is then reduced to 2 mg. daily for two to four weeks and then 1 mg. once a day for an indefinite period. Following such therapy there was a marked decrease in pain, while there was roentgenographic evidence of bone repair. Ethinyl estradiol was substituted for stilbestrol, since estradiol is a natural hormone and is, therefore, less likely to produce untoward effects. As the potency of estradiol is six to eight times that of stilbestrol, the dosage was regulated accordingly. Ethinyl estradiol caused less breast tenderness and gastric irritation than stilbestrol. The systemic effects following such treatment have been quite dramatic, the effect on the primary and metastatic disease less so.

### Hypnotics and Narcotics

Mild hypnotics and sedatives should first be employed in minimal doses, the amount being increased when necessary. Among these drugs are the new barbiturates and barbituric acid derivatives. Phenobarbital, sodium amytal, pentobarbital sodium, and seconal have been found satisfactory. The depressing action which followed the prolonged administration of the older hypnotics is less frequently observed with these newer drugs. Aspirin or phenacetin with caffeine may be combined for analgesic effect. When this form of medication is no longer effectual, then one may use codeine, or combine codeine with it. Finally, the opium derivatives will have to be employed.

As an advance in opiate medication, dihydromorphine hydrochloride (dilaudid) has now been used for almost a decade. Dilaudid has been employed in place of morphine because of certain distinct advantages it possesses. It has been said to be a stronger analgesic, requiring a dose one fifth that of morphine; it acts more quickly and is less likely to produce undesirable side-effects.

In therapeutic doses it has very little hypnotic action and does not affect intestinal peristalsis. When pain is to be relieved and sleep induced, some barbiturate should be combined with it. Dilaudid, unlike morphine, has very little effect on the gastrointestinal tract and rarely is responsible for nausea, vomiting, or constipation. Early cancer pain can often be relieved by a capsule containing  $\frac{1}{4}$  grain of dilaudid and 10 grains of aspirin. A solution of 1 grain of dilaudid in 6 oz of peptenzyme elixir provides an economical and flexible solution for oral administration, the dose being 1 or 2 teaspoonfuls.

In 1939 Eisleb and Schaumann introduced Demerol (1 methyl-4 phenyl-piperidine-4 carboxylic acid ethyl ester hydrochloride). It was immediately recognized as a potent and safe analgesic, approaching morphine in effectiveness. It was found to be most valuable as an antispasmodic. The drug is not a respiratory depressant and its atropin like effect with its sedative action makes it seem ideal for the relief of pain from visceral spasm. The dose varies between 50-100 mg orally or parenterally. In the author's experience the initial enthusiastic reports have not been confirmed in clinical trials.

Neither a patient nor a patient's relatives should judge the quantity of an analgesic or narcotic to be given, nor the time interval which should elapse between doses. Smaller amounts will be needed and the time interval should be lengthened if the medicine is given under close supervision. At times the employment of large amounts of narcotics becomes necessary and in such instances they should not be withheld.

### Specific Measures Directed Toward the Relief of Pain

Nerve pain, local or generalized, is often complained of. In the absence of definite evidence of physical involvement one may suppose that the neuritis may be due to an avitaminosis. The administration of vitamin B<sub>1</sub> may clear up many of the symptoms.

In certain cases when cancer has encroached upon nerves, diathermy has been advised and practiced. Subjectively, at times, this form of treatment has proved beneficial.

**Intravenous Alcohol Infusions**—As early as 1927 Thurz<sup>16</sup> investigated the influence of intravenous ethyl alcohol infusions upon the pain produced by inoperable malignant neoplasms. He recorded the prolonged analgesic effect following such therapeutics. The method has been used for recurrent and metastatic melanoma, mammary carcinoma, ovarian cancer, and carcinoma of the vagina.

Thurz is unable to account for the analgesic effect of the alcohol. He feels that the action is

twofold. The first action is directly upon the nervous system, and the second upon the growth itself. He states that, experimentally, the growth regresses in size following the intravenous administration of the alcohol, as a result, pressure on adjacent tissues, especially nerves, is reduced.

Careful blood and urine analyses before and during this type of medication showed no evidence of renal damage. The blood picture was unchanged.

**Technic**—For the infusions a 33 per cent ethyl alcohol solution (1 part absolute ethyl alcohol and 2 parts physiologic saline solution) is used. The initial dose is 1 cc of alcohol for each Kg of body weight. Thus a patient weighing 50 Kg (121 lbs) would receive 150 cc of the solution intravenously. The medication is administered through the usual infusion set with glass trap and the rate of drip is between 30 and 40 drops per minute. The needle should contain physiologic saline solution at the time it is introduced into the vein and the alcoholic solution should be washed out of the needle before withdrawal. If this precaution is not observed, pain is experienced and skin damage occurs. As soon as the alcohol is introduced the patient experiences transient pain along the course of the vein. This soon disappears. If the alcohol is administered at a rate exceeding 60 drops a minute there is loss of consciousness.

The alcohol is given every third day and the amount of solution is increased until 450 to 600 cc are given at one treatment.

**Response to Treatment**—The response following this treatment varies. Some patients become drowsy immediately and enjoy an undisturbed sleep which often lasts six hours. Others become noisy, laughing or crying, and exhibit all the symptoms of an alcoholic delirium, which ends in somnolence. They awake refreshed and show no ill effects from the therapy. Analgesia may be noted following the first treatment. The intravenous infusion of 33 per cent ethyl alcohol seems to be an entirely harmless procedure.

**Subarachnoid Alcohol Injection**—The injection of absolute alcohol into the subarachnoid space may be of great value in controlling the pain produced by metastasis to the lumbar vertebrae and pelvic bones from mammary and prostatic cancer, from the pressure of recurrent or inoperable gynecologic or genitourinary neoplasms. Two cubic centimeters of absolute alcohol are injected through a lumbar puncture needle. The patient should lie on the unaffected side or the side of lesser involvement, with the hips elevated. The alcohol level may be partially controlled by lowering or elevating the hips. One should not attempt anesthesia in this fashion except unilaterally, repeating the process if

there are indications for the treatment of the opposite side.

**Calcium Therapy.**—In 1933 Shear<sup>17</sup> reported the effects which followed the administration of large doses of calcium in metastatic carcinoma of bone and, in the same year, Behan<sup>18</sup> independently advanced the reasons for the relief of pain in cancer by calcium. Brunschwig,<sup>19</sup> in 1935, reported two striking results following its use. Ten per cent calcium gluconate was given intravenously in a dose of 10 cc. three times a day for one month and 10 Gm. of calcium gluconate was given three times a day by mouth. After the continued calcium medication roentgenograms demonstrated increased density in the destructive bone areas. The pain and discomfort were remarkably relieved.

In the writer's experience, medication with calcium must be continued indefinitely. At times, even more striking results are obtained with calcium therapy when it is combined with the administration of vitamins (A and D) and minute doses of thyroid extract. The diets of patients with incurable cancer are vitamin-deficient for several reasons. The amount of food taken is small. Besides, the diet is frequently liquid in character and lacks balance. The lack of vitamins A and D will affect bone, and if such vitamins are present in insufficient amounts in the diet calcium metabolism will be deranged. These vitamins may be supplied by using cod-liver or halibut-liver oil, plain or irradiated.

A change in calcium metabolism is also produced by ultraviolet irradiation. The increase of the serum calcium in the blood following exposure to ultraviolet rays may explain the beneficial effect of this type of irradiation on pain.

**Cobra Venom.**—Cobra venom was first scientifically employed at the Pasteur Institute, where it was found to be useful in relieving the severe pains accompanying malignant disease. While the work of these investigators has been reported by Macht<sup>20</sup> as being favorable, Lavedan,<sup>21</sup> at the Radium Institute in Paris, using cobra venom in 51 cases of cancer, obtained only insignificant analgesic effects and noted no influence whatever on the growths themselves.

The usual dose of cobra venom is 5 mouse units. (A mouse unit is the quantity of cobra venom solution required to kill a white mouse weighing 22 Gm. within eighteen hours after the intraperitoneal injection of the drug.) However, it is safer to use only half the contents of an ampule: 2½ mouse units. On the following day the entire content of an ampule—1 cc.—is administered. Similar doses are injected on successive days until a definite analgesia is noted. No unfavorable sequelae have been noted. Thereafter two or three injections a

week may be utilized to keep the patient comfortable. Therapy may be continued for months. Hypodermics should be given intramuscularly.

Very often cobra venom has been used as a last resort when all other therapeutic measures have failed. It was gratifying to find that in many instances analgesics and narcotics were gradually reduced and finally omitted after cobra venom had been given for sufficient lengths of time to become effective.<sup>22</sup> Some observers<sup>1</sup> have noted an improvement in their patients' mental attitude. Whether this is a true euphoria from the drug or merely the result of relief from pain and improvement in the general condition cannot be determined.

Now that so many drugs and procedures are available for relieving pain, no patient should reach the stage when he desires an operation in the hope that it may lead to death; nor should he be allowed to linger on in agony with his pain unrelieved. Unfortunately, it is still difficult, when life may likely last for many months, to counteract pain at all times, for if drugs are administered over a long period, they may eventually fail to act or may lead to demoralization which ultimately may be as distressing to the patient and his family as severe pain.

"There is no greater test of the capacity of a medical man than his ability to retain the confidence of a patient who is steadily going downhill and the management of a case of inoperable cancer will tax all the tact, knowledge, and skill of the ablest practitioner."

# THE ROLE OF HYDROTHERAPY IN REHABILITATION

H J BIREND, M D, New York City

THE definition of medicine as given in the textbook is the art and science of preventing, caring for, and assisting in the cure of disease and the care of the injured. The physician has been called the "healer" or "restorer." The process of restoring or of undergoing restoration to health or efficiency has been called rehabilitation. Rehabilitation therefore means restoration to a former normal or almost normal capacity in order to enable an individual to make his livelihood again. Since in our time of war the term "rehabilitation" or "rehabilitation program" is often being used very confusingly, it must be pointed out that "rehabilitation" is a very complex process which includes several phases: the physical and mental restoration process under the guidance of the physician, which must be followed by the vocational rehabilitation process, which will secure as its final goal full social adjustment. Krusen,<sup>1</sup> in a recent publication, has discussed all the necessary steps of physical restoration and vocational guidance for the disabled soldier. He emphasizes the importance of medical cooperation in all phases of the rehabilitation process. The physical restoration process includes all necessary therapeutic procedures. Physical therapy is only one—however, an important one—of these therapeutic procedures. Its importance must be emphasized because it can be usefully applied in all steps of the rehabilitation program even when the phase of physical restoration seems to have been completed. The object of this presentation is to draw attention to this fact and to show the usefulness of one of the branches of physical medicine in every rehabilitation program—namely, hydrotherapy.

The historical development of hydrotherapy is most interesting. Elaborate bathing establishments were used by the Romans and Greeks in the classical age. The water cure was practiced extensively and the Turkish bath routine of our day still resembles the one used by the old Romans. During the centuries to follow hydrotherapy was almost forgotten, and it is only since the middle of the nineteenth century that its use has been revived. In the interim we find mention of an unpleasant but apparently effective use of hydrotherapy, the so-called dipping chair, used in New England for the control of

scolding housewives. Hydratic procedures first were prescribed almost exclusively by lay practitioners. Physicians were slow to recognize their value because of the unique and rapid development of medical science. When the microscope was invented Virchow was the first to trace the source of disease to biologic changes of the individual body cell. "Cellular pathology" since then has been recognized. The old conception of "humoral pathology" was abandoned. The great search for scientific explanations began. Almost all branches of medicine became firmly established during the years to follow. Hydrotherapy, however, failed to satisfy the scientists. There was no rationale for it that could be presented. Winternitz, of Austria, was the first who tried to coordinate hydrotherapy with the concept of the physiology of his days. In this country Simon Baruch<sup>2</sup> published the first scientific textbook on hydrotherapy in 1899. In reading this remarkable book one cannot but admit that many of the so-called modern concepts of physical medicine were known already fifty years ago, seen, of course, in the light of the physiology of those days. Despite Baruch's publication and the many efforts by others to develop hydrotherapy ever since, this form of therapy has still remained a stepchild in medicine, even in physical medicine.

It is only recently that successful attempts have been made to correlate the so far empirical hydrotherapy with the modern concepts of physiology.

The rapid development of the specialties in medicine made the physician, to a certain extent, forget to look upon his patient as a physiologic entity. There is a definite trend noticeable in many publications now to remind the physician of his duty not to forget that the diseased organ is only a part of the body and that the entire personality should not be forgotten.

The growing number of publications on the subjects of psychosomatic medicine and geriatrics, for instance, point in this direction.

Hydrotherapy is a form of nonspecific therapy. Because of the efficiency of drug therapy and chemotherapy its value is frequently overlooked by the physician who does not realize the far-reaching reactions caused in the body by external thermal stimulation of the skin. The skin acts as a transmitter of the stimuli applied to its surface. Its many nerve fibers transmit these to the centers, which in turn influence the voluntary and involuntary processes of the body.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

Associate Physical Therapist, Hospital for Joint Diseases, New York City, and Visiting Physical Therapist, Goldwater Memorial Hospital, New York City.

The balance of the sympathetic nervous system thus can be controlled, electrolytic changes can be produced, and the endocrine system will be influenced. Since the peripheral circulation is regulated by three controls—namely, the central vasomotor center, the hormonal system acting via the circulation, and the local neurochemical axon reflex, the functional importance of the skin organ again becomes apparent. Winter,<sup>3</sup> in a British publication, has recently drawn attention to the modern aspects of counterirritation which will be referred to later on in this paper. An exchange of ions also occurs in a bath between the water and the skin tissue, which changes the structure of the skin itself. The role of the skin in controlling metabolism through heat regulation and its excretory and absorptive power is well known. Vitamins are formed in the skin. According to recent publications, it seems to play an important role in producing immunity. Agglutinins have been reported to have formed in the skin of animals after interdermal injections of paratyphoid *B. bacilli*. Antibodies are supposedly also formed in the skin. It would not be surprising if the old-fashioned method of treating measles and scarlet fever with warm baths of increasing temperature may some day be resumed. Seen in the light of the recent studies of the skin in immunity, this form of therapy at least does not appear to be ridiculous or even dangerous any more.

The condition and appearance of the skin are of great significance in order to guarantee a normal occurrence of all these reactions for the benefit of the patient. In chronic diseases the skin assumes a pale and unhealthy appearance. Here true dermatotherapy is in order.

Because of its long-known effects on the circulation, the nervous system, and the muscular system, hydrotherapy has been extensively used in all kinds of pathologic conditions. Experience, however, shows that its clinical application is largely limited to local use or to a limited number of rheumatic diseases or orthopaedic disorders when used generally. The whirlpool bath is the most-used hydriatic appliance in military and civilian hospitals because of its pain-relieving and relaxing effect and the marked stimulative effect it exerts on the circulation. Mechanically it will remove pus or necrosed tissue from acute or sluggish-healing wounds. The hot tub-bath is used for the treatment of spasm and pain in rheumatic or allied disorders. The third hydrotherapeutic modality frequently used in hospitals is the Scotch douche. It is mainly applied as an after-treatment to some other form of heat therapy, usually the cabinet bath, which is not at all a hydrotherapeutic procedure but an application of radiant heat. In recent years

underwater exercises in the pool or specially constructed tank have become very popular in post-operative orthopaedic conditions and in paralysis cases. All the hydrotherapeutic appliances mentioned so far are usually being used routinely with very little attention paid to the vast possibilities of adjusting the temperature, the duration of the application applied, the size of the area of the body involved, and the mechanical pressure. Because of their indiscriminate use the results vary; sometimes they are very good; on other occasions they are disappointing. Because of these disappointments and the empirical rationale hydrotherapy has been neglected by the medical profession and this is also the reason why it is mostly used locally and in surgical or orthopaedic cases only. From what has been said about the role of the skin organ as a transmitter of external stimulation, it follows that hydrotherapy can be efficiently used in many other pathologic conditions beside those mentioned above. Its important role in reconditioning the entire personality will be considered here.

The present war situation will affect the state of health of the entire population in many respects, which makes an extensive reconditioning program necessary during and even more after the war. Two groups of injury can be classified as arising from the war effort:

1. Direct injury or disease suffered in active combat or in the war industries. This is obvious.

2. Indirect injury caused by the tremendous change of the condition and way of life which a large part of the population has to undergo. The structure of many families has changed. The earner has gone to war; other members of the family have to pitch in. Accustomed habits of living, of nutrition, of clothing, of transportation, of work had to be changed and adjusted. These changed habits, combined with the worry about those in active service, will cause a great strain on many individuals. The symptomatology of neuromuscular hypertension and of physical and mental fatigue will be more and more observed in our patients. Complaints of headache, of dizziness, of palpitation, of indigestion and other gastrointestinal symptoms, of aches and pains all over, have become more and more frequent. The number of the so-called functional, not organic, or nonspecific diseases will rise. Not all these patients are sufferers from an original mental instability, although it should not be forgotten that the symptomatology of primary neurotic individuals will grow immensely. All these patients will deserve treatment in order to make them valuable participants in our postwar reconstruction. Drug therapy alone will not suffice and psychotherapy will either not be sought or cannot be afforded.

Physical medicine comes in here, and hydrotherapy, because of its nonspecific nature, should be accorded a front place in the reconditioning program.

For the first group of direct war casualties some of the hydropathic modalities have been mentioned already. Again it should be emphasized that even in treating local injuries and diseases more use should be made of those hydrotherapeutic procedures which involve the entire body. It is our experience that recovery from local conditions is hastened when the entire body is exposed to the external stimulation of the warm or cold applications, for the reasons given above. For the same reason hydrotherapy has its definite place in internal medicine. Almost all diseases of the circulatory system can be benefited by hydrotherapy if it is applied correctly. Local and general baths the temperatures of which are gradually increased or decreased will exert an important influence on the distribution of the blood, will change the blood pressure, and will influence congestion of the pulmonary circulation. The heart itself is influenced reflexly by thermic stimulation and a weak myocardium therefore can be strengthened. Local cooling of the heart region can give quick relief in tachycardia and has been proved to be of value in acute endocarditis. Towel baths, sponge baths, half baths, brush baths will promote dilation of the peripheral and skin vessels, will ease the circulation, and will reflexly influence the heart and the respiration. The use of balneotherapy in the form of carbon dioxide or oxygen baths for the treatment of acute and chronic circulatory and vascular disorders must be mentioned here, and is important in spa therapy.

In attacks of bronchial asthma we can use hot chest compresses, sitz baths of increasing temperature, and half baths successfully as an adjunct to drug therapy in order to relieve bronchial spasm.

A Priessnitz compress applied for a case of acute or chronic bronchitis is still a simple and efficient procedure, especially for children. When it is applied technically correctly there is no danger of the patient's contracting pneumonia, as so many parents dread. The chest compress, because of the reactive vasodilatation it brings about, will benefit the patient immensely. It diminishes coughing, stimulates the vasomotor system, and helps expectoration. Restless children will fall asleep almost immediately after its application.

In diseases of the kidneys warm baths will improve their circulation and will help restore their function to normal. Warm sitz baths are an old standby for inflammatory conditions of the bladder and the pelvic organs.

In diseases of the gastrointestinal tract the spasm- and pain relieving effect of wet hot applications on the abdomen are well known.

It almost appears to be absurd to mention even briefly here all these well-known and old-fashioned applications and some of their indications in internal medicine. But in our days of highly developed diagnostic, drug, electro- and other therapy they have been widely neglected and almost forgotten. The modern physician is not too much impressed by the old-fashioned hydropathic procedures. Our colleagues and nurses in the combat zone where the well-equipped physical therapy department and drugstore are not available should feel differently. Even when hot water is not available a cold, stimulating compress may become a life savior.

A few words must be said about the so called rheumatic diseases. Winter<sup>2</sup> and others have drawn attention to the significance of the skin in the causation of rheumatism. The beneficent effect of counterirritant measures in the treatment of rheumatic diseases is well known. Since hydrotherapy always involves stimulation of the skin, it is one of the oldest forms of therapy for these conditions. In a hydropathic application the three factors of temperature, time, and mechanical pressure can be greatly varied and adjusted to individual needs. Baruch<sup>2</sup> already has used the variations of the Scotch douche with good results. Where a Scotch douche is not available, brushing of the skin in a warm bath will produce similar results. The combination of water with the galvanic current in the form of hydrogalvanism has been revived recently<sup>4,5</sup> and permits a wide variety of skin stimulation. The physiologic effects of the galvanic current can be extensively utilized in a bath and have shown remarkable results in painful rheumatic conditions.

There is now to be considered the second group of diseases which are more or less of a functional character. Here it is our purpose to recondition the fatigued personality. Because of the fact that a rationale of hydrotherapy could not be established for a long time, its use has been branded by some physicians as purely suggestion. The foregoing discussion has shown that great and objective changes in all systems of the body, including the psychologic state of the patient, can be caused by hydropathic procedures. Stimulation of the body surface has definite consequences. It is, however, important to be aware of the reactions which may occur in order to guarantee an undisturbed change from abnormal to normal physiologic conditions.<sup>5</sup>

The procedures used for the treatment of functional condition are those involving the entire body surface. They can be classified according

to their strength of stimulation, which in turn depends upon the temperature of the application, the length of time for which it is applied, and the size of the area of the body it involves. The same ablution, the same sheet bath rub, the same partial bath, the same Scotch douche, the same full bath therefore may serve all purposes. It may have a sedative, a neutral, or a stimulating effect. This is why hydrotherapy lends itself admirably to nonspecific treatment if used correctly, and why disappointments are in order if it is used by unskilled hands. Time does not permit the enumeration of all the various hydrotherapeutic procedures used in the treatment of disturbances of the sympathetic nervous system or of the endocrine imbalances, of neurocirculatory asthenia, or of the true neuroses. Symptoms such as restlessness, sleeplessness, palpitation, dizziness, nervous headaches, and abdominal spasms will respond in a very gratifying way to hydrotherapy.

Here again all those appliances should be used which involve the entire body: the half bath, the brush bath, the sheet bath, the galvanic bath—just to mention a few. They form an excellent adjunct in the treatment of the convalescent phase of the injured and diseased because of their tonic effect on the circulation and all the other systems of the body.

In a rehabilitation program, therefore, hydrotherapy should by no means be restricted to the physical restoration period of a more or less local injury or disease. Its use must not be limited to the hospital. The rehabilitation centers of the Army, the Navy, the Veterans Administration, and of civilian institutions have developed an extensive system to restore and maintain physical fitness. In preparation for correct daily activities before taking up strenuous exercises or games, hydrotherapy should be used in the rehabilitation centers not only in the form of the recreational pool but also in form of appliances which are adjustable to individual needs.

During the vocational guidance and vocational training period correctly applied hydrotherapy will also help to keep the trainee fit. Properly administered hydrotherapy departments should be installed in rehabilitation centers and in the industries rather than just bathing establishments and shower rooms.

At this time the importance of spa therapy in rehabilitation must be mentioned. Hydrotherapy is one of the important factors in spa therapy. Even to mention it briefly would transgress the scope of this paper. It is hoped that the discussion later on will develop in this direction.

The size and the equipment of a hydrotherapy department depend on the character of the hospital or institution. One can run a good

hydrotherapy department with equipment limited to two surgical bathtubs plus one large-sized bathtub and bath brush. Every hospital should have a well-equipped hydrotherapy department in addition to its usual physical therapy equipment. The layout and equipment for a short-stay hospital certainly will differ from those of a long-stay hospital. The minimal equipment should consist of an institutional-sized bathtub, a whirlpool bath, a hydrotherapy table for the application of douches, and a steam jet. Tanks, pools, and other equipment can be added according to individual needs.

The best-equipped hydrotherapy department cannot work properly unless its technical personnel is well trained and the physician in charge is assured of the cooperation of the medical staff. Much explaining, enlightening, and training have to be done in this respect. In our department at the Hospital for Joint Diseases we have given more than 75,000 treatments during the past ten years. The results are very satisfactory and the cooperation of the medical staff is increasingly excellent.

At Goldwater Memorial Hospital the hydrotherapy department is an important part of the physical therapy. During the past five years 112,552 treatments have been given there. Hydrotherapy comprises about 30 per cent of the activities of the Physical Therapy Department. The large number of treatments given in the past ten years and the excellent results obtained in so many cases have convinced us of the great value of the hydrotherapeutic procedures used.

In conclusion, one more thought should be expressed. The rehabilitated individual finally returns home, and most homes have a small hydrotherapy department—the bathroom and its tub and shower. Here hydrotherapeutic technic is used at its worst. Too hot and too cold showers and baths given for too long or too short a period and with incorrect pressure may cause great harm. The daily bath and its routine can be the cause of much trouble. Very little attention is paid by the medical profession to the patients' daily bathing habits. A healthy vasomotor and circulatory system is able to adjust itself and even to benefit from strong stimulations. A weakened one may suffer definite harm. It is therefore necessary to educate the patient and the public how to use the applications of water correctly. Much can be done in this respect. Hydrotherapeutic home treatments then can be given with great benefit to the patient. Unnecessary trips to the clinic and unnecessary expenses associated with it can be avoided. Adjuvant home treatment has not only a medical but also a great social aspect.

ALL BABIES IN WAR TIME OR PEACE TIME  
NEED *Calcium · Phosphorus · Vitamin D*

these times even with war liberal rationing, there may be an occasional scarcity of the products which are considered ample and dependable sources of Calcium—Phosphorus—and Vitamin D. In consequence, both the maternal and child's diet may not contain enough of these foods for daily needs.

Always needed is vitamin D—the poorest distributed of the vitamins—and when the diet must be fortified with calcium and phosphorus, it is convenient to give a supplement such as Squibb Dical-

cium Phosphate Compound with Viosterol which is available in two forms, tablets and capsules.

One tablet (wintergreen flavored) 3 times daily supplies a total of 7.8 grains of calcium (about one-half the daily requirement) and more units of vitamin D than 8 teaspoonfuls of Squibb Cod Liver Oil.

Two capsules are equivalent in calcium, phosphorus and vitamin D to 1 tablet.

The tablets are supplied in boxes of 51 and 250; capsules in bottles of 100, 250 and 1000.

Authorities Agree —

# NUTRITION STARTS WITH BREAKFAST!

And whole grain or enriched cereals are a fine means of supplying nourishment on which to start the day.

A GREAT share of the responsibility for putting over the National Nutrition Program rests on the capable shoulders of the Medical profession. And it is doing a splendid job.

But here's a way that job can be made easier — for it enlists flavor, real appetite-appeal, in making sure people get the better breakfasts they should have.

Whole-grain oats are recognized as one of our best sources of grain protein. They are high in energy content and supply natural

Vitamin B<sub>1</sub>, calcium, nutritional iron and phosphorus.

To this high nutrition value, H-O Oats adds the taste-appeal of pan-toasting. Cooked slowly and evenly over the dry heat of open fires, H-O acquires a distinct and tantalizing flavor that makes an instant hit.

With such appeal in every bowl, folks will need no urging to eat the kind of breakfast cereal they should have for sound nutrition. Try H-O Oats yourself and see if they don't make a tastier breakfast as well as a nutritious one.

- ★ Oatmeal leads all other whole-grain cereals in proteins. Oatmeal supplies 64 grams of proteins per pound.
  - ★ Oatmeal leads all other cereals in food-energy. Oatmeal supplies 1,720 calories per pound.
  - ★ Oatmeal leads all other cereals in fat content. Oatmeal supplies 7.4%.
- Besides generous supplies of Vitamin B<sub>1</sub>, niacin and nutritional iron.

#### How H-O Oats Differ

H-O Oats are the only oats that are pan-toasted—cooked over dry heat that leaves in all the concentrated fluffy oat goodness. Result? Flavor! Wonderful flavor made even more attractive by precision-cutting for fine, even texture and lighter, creamier oatmeal. H-O Oats do taste different. Deliciously different. Try 'em yourself—you'll agree

The BEST FOODS, Inc.

[Continued from page 2258]

The question frequently arises: Can hydrotherapy be replaced by other methods of physical medicine? It certainly does not constitute a panacea which will replace other accepted forms of therapy.

In rehabilitation, however, it should be developed to a high degree. There is hardly any other method that can contribute more to the final cure of major and minor injuries and to the restoration of confidence and morale.

### Discussion

Dr. Walter S. McClellan, *Saratoga Springs*—Two portions of this presentation are of particular interest to me. First, the importance of the skin organ as a receptor of impulses which act on the system through the delicate end organs of the nerves, and the fine network of the capillary system, which has not received the emphasis which it merits. The wide extent of the physiologic effects of hydrotherapy emphasizes the clinical importance of a thorough knowledge of these skin mechanisms. The speaker has today, and in other presentations, focused our attention on this matter. More investigations in this direction are in order.

In the second place, the speaker has mentioned spa therapy and balneotherapy but was not able to develop this phase of his subject. Spa therapy, which includes a program of treatment built up around either mineral waters or peloids (muds) as the keystone and utilizing accessory forms of physical treatment, rest, recreation, and dietotherapy, can play its part in the program of rehabilitation. It is applicable particularly in chronic cardiovascular conditions, rheumatic ailments, post-traumatic limitations, and functional nervous disorders of the less severe type. At the Veterans Facility at Saratoga a recent report stressed the good response of the

patients with chronic rheumatic and post-traumatic ailments following the use of mineral baths and local accessory heat treatments.

Krusen has pointed out the interest of the Army and Navy in this field. They are using some of our spa facilities, such as White Sulphur Springs, West Virginia, Glenwood Springs, Colorado, and others. In spas the therapeutic program stresses both the physical and the mental rebuilding which Dr. Behrend has described.

Avoidance of misuse and discredit of hydrotherapy can only be attained by a more thorough understanding of its proper application and by the accurate determination of its indications. In order to accomplish these goals, more physicians and trained personnel with a knowledge of hydrotherapy are required. The inclusion of instruction in hydrotherapy as one division of physical medicine must have a place in our medical schools both for the undergraduate and for the postgraduate physician. Then hydrotherapy and physical medicine as a form of therapy will find their proper place in relation to all types of treatment which the physician must use in proper proportions to accomplish the maximum relief for his patients.

Dr. Robert Muller, *New York City*—In rehabilitation, the after-care of patients who have been operated upon deserves special consideration. Orthopaedic surgery makes frequent use of metal nails, screws, plates, and caps which are permanently embedded in the bones. Whenever such conductors are in the tissues, the application of electric currents, short wave, etc., is contraindicated.

After operations, in the neighborhood of the incision, regions of anesthesia are present, where a burn may result when too much heat (hot-water bottle, diathermy, etc.) is applied.

Plastic surgery is extensively used in rehabilitation. Here the application of heat on the various skin grafts and flaps is especially dangerous, as the circulation in the anesthetic areas is poor. Necrosis of a full thickness of skin graft can follow indiscriminate application of heat.

In these three conditions—(1) whenever metal is present in the area to be treated, (2) when numbness fails to warn the patient of excessive heat, (3) when the area is poorly circulated—the only safe form of application of heat to promote healing is warm water in the form of a whirlpool bath or other hydrotherapeutic procedures.

### EXHIBIT OF NAVAL MEDICINE AT NATIONAL GALLERY OF ART

A collection of one hundred paintings and drawings of naval medicine was put on view at the National Gallery of Art, Washington, D.C., September 10, where it remained until October 8, after which the collection was sent on tour throughout the United States.

The artists whose works were exhibited in the program and the phases of naval medicine which they covered are as follows: Hospital Corps Training, depicted by David Stone Martin and Irwin

Hoffman at the Navy Medical Field Service School, Camp Lejeune, North Carolina; Combat Action, depicted by Joseph Hirsch and Kerr Eby at Pearl Harbor, New Caledonia, New Guinea, Guadalcanal, Tarawa, and Bougainville; and Treatment of Convalescents; these were depicted by Carlos Andreson and Julian Levy at the U.S. Naval Hospital, Portsmouth, Virginia, and National Naval Medical Center, Bethesda, Maryland.—*J.A.M.A.*, Sept. 16, 1944

Authorities Agree —

# NUTRITION STARTS WITH BREAKFAST!

And whole grain or enriched cereals are a fine means of supplying nourishment on which to start the day.

A GREAT share of the responsibility for putting over the National Nutrition Program rests on the capable shoulders of the Medical profession. And it is doing a splendid job.

But here's a way that job can be made easier — for it enlists flavor, real appetite-appeal, in making sure people get the better breakfasts they should have.

Whole-grain oats are recognized as one of our best sources of grain protein. They are high in energy content and supply natural

Vitamin B<sub>1</sub>, calcium, nutritional iron and phosphorus.

To this high nutrition value, H-O Oats adds the taste-appeal of pan-toasting. Cooked slowly and evenly over the dry heat of open fires, H-O acquires a distinct and tantalizing flavor that makes an instant hit.

With such appeal in every bowl, folks will need no urging to eat the kind of breakfast cereal they should have for sound nutrition. Try H-O Oats yourself and see if they don't make a tastier breakfast as well as a nutritious one.

★ Oatmeal leads all other whole-grain cereals in proteins. Oatmeal supplies 64 grams of proteins per pound.

★ Oatmeal leads all other cereals in food-energy. Oatmeal supplies 1,720 calories per pound.

★ Oatmeal leads all other cereals in fat content. Oatmeal supplies 7.4%.

Besides generous supplies of Vitamin B<sub>1</sub>, niacin and nutritional iron.

## How H-O Oats Differ

H O Oats are the *only* oats that are pan-toasted—cooked over dry heat that leaves in all the concentrated fluffy oat goodness. Result? Flavor! Wonderful flavor made even more attractive by precision-cutting for fine, even texture and lighter, creamier oatmeal. H-O Oats do taste different. Deliciously different. Try 'em yourself—you'll agree.

The BEST FOODS, Inc.

# Diagnosis

## CLINICOPATHOLOGIC CONFERENCES

### FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

The patient was a 40-year-old Italian housewife first admitted on July 7, 1942, complaining of headaches, nervousness, and restlessness of one year's duration. The symptoms were increased at the time of the patient's menstrual periods and for the four days preceding admission were so severe that the patient was unable to sleep or eat. The past history was negative except for otitis media in childhood and rheumatic fever at the age of 14.

Physical examination on admission revealed an agitated, poorly nourished, chronically ill white woman. The essential positive findings were moderate thinning and tortuosity of the vessels of the fundi. The heart was slightly enlarged to percussion. Soft systolic murmur was present at the aortic area. The blood pressure was 220/120. The abdomen was soft. The liver was palpable 2 finger breadths below the costal margin. The spleen was not felt. The palms showed numerous red, nodular masses deep in the subcuticular tissues.

Blood smears and counts were normal. Examination showed a specific gravity of 1.022; albumin, 2 plus; a few granular casts, and a few white and red blood cells. The blood Wassermann test was negative. The blood nonprotein nitrogen was 32; carbon dioxide combining power was 33 volumes per cent. The blood cholesterol was 167; erythrocyte sedimentation rate was 115 mm.; blood agglutinins (3x) negative. The urine showed albumin 1 to 2 plus, occasional granular casts, and red and white blood cells. Electrocardiogram showed marked myocardial changes.

*Course.*—The temperature ranged between 101 and 102 F. for two weeks and then became normal. Shortly after admission the patient developed nuchal rigidity and a positive Brudzinski. The spinal fluid was normal, however, and by the fourth day the neck stiffness was found to be voluntary because of marked tenderness of the cervical spine. Generalized glandular enlargement, a barely palpable spleen, herpes of the upper lip, and spread of the palmar rash to the upper part of the chest were also noted at this time. By the second hospital week the patient appeared improved, the palmar rash was fading, the eruption on the chest became macular and papular with whitish centers, the spleen was definitely palpable, the fingers began to show clubbing, and the left wrist joint became

swollen, tender, and reddened. One observer noted a diastolic murmur at the apex at this time. By the third week the patient was much improved, the rash was gone, and the spleen was no longer palpable. She was sent to the country on July 30, 1942, having received only symptomatic treatment.

The patient was readmitted on October 9, 1942. While in the country she had had a recurrence of all her symptoms, including the rash and wrist joint involvement, which gradually cleared after two weeks. At the time of her menstrual period in September she developed an eruption on the right ear, a "bruise" on the left ankle, and a painful nodule in the left calf. During her October period an eruption on the left ear appeared. The patient sought readmission because of recurrence of severe, constant pain in the head and back of the neck for three weeks and vomiting for four days.

*Physical Examination.*—The blood pressure was 186/96. The positive findings were the same as before, except that there was now a raised, red, confluent eruption on the left ear lobe, a large ecchymosis of the left ankle, a tender nodule in the left calf, a systolic murmur over the whole precordium, the liver was palpable 3 fingerbreadths below the costal margin and tender, and the spleen was enlarged and tender. The laboratory findings were unchanged. The blood nonprotein nitrogen was 32 and the albumin-globulin ratio was 4.6:4.0. Biopsy of the muscle and of the nodule in the calf was taken. The patient was afebrile. The blood pressure varied between 170/84 and 218/108. Her symptoms cleared gradually with no specific treatment and she was discharged on November 1, 1942.

The patient was readmitted nine days later November 10 because of a cold, heavy feeling in the left lower leg and needle-like pain radiating from the left foot up the leg.

*Physical Examination.*—The blood pressure was 230/130. At this time a small hemorrhage was noted in the macula of the right ocular fundus. The heart murmur and the enlarged liver and spleen were unchanged. The left foot was pale, cold, and tender, with mottled cyanosis and absent dorsalis pedis pulsations; early clubbing of the fingers was again noted and there were a few macular eruptions over the legs.

[Continued on page 2264]

**I**N COLONIC STASIS putrefaction often induces systemic disturbances. In the atonic colon multiplication of putrefactive bacteria occurs, thus restoration of a normal aciduric flora is indicated to inhibit putrefaction.

For this purpose, implantation of the lactic acid producing acidophilus bacilli—indigenous to the intestinal tract—is logical corrective therapy.

Neo-Cultol®, a chocolate flavored mineral oil jelly containing *B. acidophilus* is pleasingly palatable and non-habit forming. It exerts a dual clinical effect . . . the antiputrefactive action of the *B. acidophilus* plus the mechanical action of the mineral oil.

[Continued from page 2262]

**Laboratory Data.**—The red blood cell count was 4.20 millions. Hemoglobin was 12 Gm. The white blood count was 9,450, with polymorphonuclears, 88 per cent; platelets, 250,000. Blood nonprotein nitrogen was 30. Erythrocyte sedimentation rate was 70. Albumin-globulin ratio was 4.1:3.4. Bleeding time was 6 minutes; clotting time, 5 minutes 15 seconds. Prothrombin time was slightly prolonged. A blood culture was negative. Urine examination showed a specific gravity up to 1.021; albumin, 1 to 2 plus; an occasional trace of glucose, occasional granular casts; and red and white blood cells. Oscillographic readings were: left knee, 9 units; left ankle, 0 units; right ankle, 2 units.

**Course.**—The temperature rose to 104 F. on the fifth day, fell gradually to 99–100 F., where it remained for several weeks and then became normal. The blood pressure did not drop below 200/110. Several days after admission a rash appeared over the back of the arms, consisting of discrete pink, warm, itchy, raised macules. The palms again showed intradermal red papules and there was a suggestion of a butterfly rash over the face. On November 13 a sympathetic block was done, with slight improvement in the left leg. On November 16, 6 cc. of ammonium sulfate were injected intrathecally with no beneficial result. At the time of the injection the cerebrospinal fluid pressure was 300 mm. water, the fluid was cloudy and showed 300 cells, mostly polymorphonuclears, and a protein of 180, but there were no meningeal signs at this time. The left foot gradually became gangrenous and constant sedation was required to relieve the pain. On December 1 the patient suddenly developed lower abdominal and right costovertebral angle pain and tenderness, frequency, and passage of small amounts of urine. Coincident with this there was a slight rise in temperature, elevation of the white count to 20,000 with 89 per cent polymorphonuclear, and increase in the cellular elements in the urine. The episode subsided spontaneously within a few days. Examination of the ocular fundi on December 17 showed, numerous superficial hemorrhages and soft fluffy exudates, with one hemorrhage suggestive of a true petechia, marked tortuosity of the vessels, and marked auriculoventricular compression.

The lower left leg was amputated on January 9. The postoperative course was uneventful and the patient was discharged on March 2, 1943. Examination of tissue from the amputated leg was reported as showing chronic myositis.

The final admission was on April 17, 1944, when the patient entered the hospital because of headache, and weakness, which had been

periodically present ever since the onset of her illness.

**Physical Examination.**—The blood pressure was 250/110. The patient appeared poorly nourished and chronically ill. The pupils reacted sluggishly. The fundi showed old and fresh hemorrhages and papilledema, and there was a macular star on the left. The neck veins were distended and filled from below. The lungs were clear. The heart was enlarged and the precordial pulsations were marked. A soft systolic murmur was present at the apex and the base. The liver was palpable 3 fingerbreadths below the costal margin and was moderately tender. The spleen was not felt. No rash was noted.

**Laboratory Data.**—The red blood cell count was 2.76 millions, and the hemoglobin 5 Gm. There were 9,900 white cells, with 70 per cent polymorphonuclears, 2 per cent lymphocytes; transitional cells, 26 per cent; stab cells 6 per cent. Urine examination showed a specific gravity of 1.011; albumin, 3 plus; glucose, 1 plus; and a few white blood cells. Blood nonprotein nitrogen was 112. The electrocardiogram showed marked myocardial damage.

**Course.**—The temperature varied irregularly between normal and 101 F. The patient vomited frequently and appeared to suffer from generalized pains. On April 22 a pericardial friction rub was noted and the lungs showed moist rales over both lower halves. The patient became progressively weaker, had several generalized convulsions on April 29, and died on May 1, 1944.

### Discussion of the Case

DR. CHARLES H. NAMMACK: The question of causation is the main one in this case, but we cannot hope to know the answer without the postmortem findings. The case fits the criteria for lupus erythematosus disseminata. I think we must conclude that there were some valvular changes, since changing murmurs were noted.

DR. EMANUEL APPELBAUM: I saw this patient on her first admission and I believe that I was the first to suggest the diagnosis of lupus erythematosus disseminata. In the differential diagnosis periarteritis nodosa cannot be dismissed but the case does not fulfill the pattern of this disease. For instance, the joint manifestations, the lack of leukocytosis, and the absence of eosinophilia are features against that diagnosis.

Rheumatic fever should have been considered. There was a history of past rheumatic fever, of joint pains, and of exacerbations and remissions. In addition, rheumatic fever does often show severe diffuse vascular disease. Furthermore, erythematous skin lesions may occur in rheuma-

[Continued on page 2266]

Two additional new developments to aid electro-medical diagnosis and treatment —

by the Electro-Physical Laboratories, Inc.

## EPL Electro-Encephalographs

**MODEL PE-2 . . .**  
a two-channel portable machine.

*Available in stationary form in any number of channels, such as Model SE-6 shown here.*

Both of these electro-encephalographs operate efficiently in most locations without the use of a shielded room. The results achieved are equal to those obtained by any permanently installed instrument utilizing a shielded room. This is true even at ten microvolt sensitivity, with multi-channel bi-polar connections. In the portable models, all connecting cables, electrode leads, and other necessary accessories can be carried in both boxes, and by one man. Box size . . . 13" x 13" x 12". Weight of amplifier box . . . 30 pounds. Weight of writer box . . . 38 pounds. The stable amplifier, of straightforward design, radically reduces interference, and permits the taking of encephalograms in heretofore impossible locations. New methods in ink or inkless writing (as preferred) and other electro-mechanical features make for new ease and reliability of operation.

## EPL Electric Shock Machines

Devoid of all unnecessary control knobs or meters. A newly developed timing circuit provides shock current durations over an unusually wide range . . . .1 to .6 seconds in standard models, and up to 4 seconds on special order. This circuit holds its adjustment regardless of the voltage of the power supply line. Light in weight . . . 10 pounds. Small in size . . . 12½" wide x 9½" high x 7" deep.

*More detailed information about all EPL electro-medical developments—Electrocardiographs, Electro-Encephalographs and Electric Shock Machines—will be forwarded to you upon request. Address, Dept. G-10.*

a division of the ELECTRONIC CORPORATION OF AMERICA

[Continued from page 2264]

tic fever. These may take a papular form or be margined.

The papular type of lesion may be very much like the lesions seen in this case. Cerebral symptoms likewise occur on rare occasions in rheumatic fever. Glomerulonephritis, through a rare manifestation of rheumatic fever, has been observed in both the acute and the chronic forms of this disease. However, there are many features, such as the presence of lymphadenopathy and the absence of leukocytosis, which are against the diagnosis of rheumatic fever.

Dermatomyositis does not fulfill many of the criteria. It may be noted that certain investigators consider dermatomyositis, periarteritis, and lupus erythematosus disseminata as a common group of diseases due to disturbance of collagen tissues. In regard to the demonstration of myositis in the biopsy, it should be noted that such changes in muscle are not limited to dermatomyositis but may be found in lupus erythematosus disseminata.

Lupus erythematosus disseminata occurs in two forms—the acute, which runs a short, fulminating course, terminating in death, and the chronic form, which has a prolonged course, with exacerbations and remissions. This case would fit into the latter category. The other features favoring the diagnosis of lupus erythematosus disseminata are: prolonged fever, joint involvement, splenomegaly, rash, renal involvement, and bleeding tendency as manifested by purpuric lesions and ecchymoses. The features lacking in this case are evidence of bone marrow depression (anemia, leukopenia, and thrombocytopenia), and polyserositis. Disturbances in the blood picture may not become apparent until toward the end of the clinical course. It is possible that thrombocytopenia was present since only two platelet counts were done. The terminal pericarditis may have been a manifestation of serous membrane involvement.

Lupus erythematosus disseminata is essentially a disease of the epithelial and mesothelial tissues. Endocardial involvement may be lacking or may be an atypical verrucous endocarditis. This has been described in detail by Dr. Libman and has been known as Libman-Sacks' disease. Whether it is a distinct clinical entity is problematic. Most likely it is a phase of lupus erythematosus disseminata. The lesions in this form of endocarditis are frequently mural or pocket lesions, or involve the under surfaces of the valve. On rare occasions one observes a nonbacterial, thrombotic form of endocarditis. The gangrene of the leg could be explained on the basis of either localized thrombosis due to disease of the endothelium or to embolization. Indeed, the kidney

lesions are characterized by localized thrombi in the glomerular tufts.

Brain involvement may be seen in any of the diseases considered in the differential diagnosis. In rheumatic encephalopathy the brain may show thickened vessels with perivascular serous exudate. In lupus erythematosus disseminata there may be localized thrombi with multiple small areas of encephalomalacia. The reaction to these might account for the increased cell count and high protein content found in the patient's cerebrospinal fluid.

A review of all these features strongly favors the diagnosis of lupus erythematosus disseminata.

DR. MAX TRUBEK: I saw the patient only on her last admission when the picture was that of diffuse arteriolar sclerosis such as is seen in essential hypertension. The eyeground changes, I found, had been present apparently two years previously. Hypertension was constant and marked in this case and early hypertension is not characteristic of lupus erythematosus disseminata. The cardiac picture was just one of hypertrophy. The murmurs were not striking and not constantly found. All the palpable arteries were thickened. There were dilated veins on one side of the chest, which led us to consider the possibility of vena caval obstruction.

The urine showed good specific gravity originally and the intravenous pyelogram taken on the first admission is too good to fit in with extensive renal damage. Probably the vascular changes were the primary ones, since the renal failure was very late in the course of the patient's illness.

DR. ARNOLD KOFFLER: It is possible that the patient had essential hypertension before the acute disease was superadded. Rheumatic fever was not seriously considered. The joint involvement was minor, only the wrist being involved. The electrocardiographic changes were not those usual in rheumatic fever; in fact, the pains indicated muscular rather than joint involvement.

DR. A. W. FREIREICH: The Drs. Reifstein reported seventeen cases of lupus and related diseases which came to autopsy. The only constant postmortem finding was involvement of the serous membranes. All of the cases showed a pleuritis, many of them showed a pericarditis, and a few showed a peritonitis. The absence of any of these findings is a serious drawback to the diagnosis of lupus erythematosus disseminata.

DR. KOFFLER: This case is difficult diagnostically but very interesting. On the patient's first admission, I considered this to be an acute illness superimposed on some chronic pathology—that is, either essential hypertension or chronic

[Continued from page 2266]

glomerulonephritis. The palmar rash, which was macular but principally purpuric, the temperature, severe headache, and meningismus suggested several diseases, but principally Rocky Mountain spotted fever. However, the course of the illness, the clinical features, and the persistent absence of positive agglutinations ruled out this diagnosis. We were confronted with a variable group of disease into which this case might fit. Specifically, we can list the following:

1. Lupus erythematosus disseminata.
2. Periarteritis nodosa.
3. Dermatomyositis.
4. Subacute bacterial endocarditis.

Without the postmortem findings, I am sure that the diagnosis cannot, with any accuracy, be made.

Several diseases can be ruled out with some degree of certainty. Subacute bacterial endocarditis can be dismissed in the absence of a single positive culture, in spite of the possibility

TABLE 1

<i>Lupus Erythematosus Disseminata</i>	<i>Dermatomyositis</i>
Sex: Predominantly female	Often occurs in males and in a wider age group
Fever: Variable, irregular, prolonged	Same type
Cutaneous Lesions: Lupus, purpurae, petechiae with white centers	Edema and telangiectasis of eyelids; atrophic areas over fingers and sometimes over the larger joints and trunk; areas of erythema over muscles involved; hypertrichosis; peculiar whitish areas on the oral mucous membranes and tongue
Muscles: Myositis	Marked tenderness
Joints: Arthralgia, occasional "rheumatoid arthritis" reported	Are spared, but involvement of muscles and tendons may cause contractures
Heart: Myocardial changes are not characteristic; there is usually low voltage. Endocardial verrucae described by Libman and Sacks. Pericardial rub may be present; effusions are frequent. Systolic murmurs are frequent but may not indicate that an endocarditis is present	Rarely involved; tachycardia is frequent
Lungs: Pleural effusion is common; friction rub may be present; bronchopneumonia is frequent	Rarely involved
Lymph Nodes: Frequently enlarged	Less commonly affected
Spleen: May be enlarged but as a rule it is not markedly	Not large
Blood: Progressive anemia	Secondary anemia
Kidneys: There is a diffuse vascular glomerular disease and occasionally nephritis	Changes not usually significant
Hypertension: Is usually not marked, but may occur	Not usually present
Ophthalmoscopic findings: Hemorrhages and exudates may be present. Occasionally there is papilledema	No changes
	Cerebral Symptoms: Irritability, convulsions

of embolization to the left leg, but we cannot definitely state that this was an embolic phenomenon. It may have been the result of local thrombosis resulting from arterial disease.

Periarteritis nodosa was never completely ruled out and still remains a possibility in spite of one negative biopsy report.

The diseases which we must consider to be most probable are lupus erythematosus and dermatomyositis. From the outline of the clinical features of each shown in Table 1, it becomes evident that these features overlap considerably.

In considering lupus erythematosus disseminata, we must include Libman-Sacks' disease, which need have for its criteria neither the cutaneous lupus lesions nor the endocardial lesions first described by the authors. The cause of this disease is not known, as that of lupus erythematosus, to which it rightfully belongs; it occurs predominantly in the female. Its duration may be months or years. The fever is variable and irregular; arthritis and arthralgia may be present. The cutaneous lesions may be of several types—lupus, dermatomyositis, petechiae with white centers, and purpurae. The lymph nodes may be enlarged. The kidneys show diffuse glomerular disease—occasionally nephritis and usually no hypertension. Spontaneous serous effusions occur. Pericarditis is very frequent. Pleurisy with or without effusion may be present. The muscles may show myositis and occasionally dermatomyositis. The heart may show a systolic murmur. The spleen is moderately enlarged. There is usually a progressive secondary anemia. It is interesting to note that Christian, in 1935, described a disease with long-continued fever and with inflammatory changes in the serous and synovial membranes and essential glomerulonephritis—a clinical syndrome of unknown cause.

Banks, in 1941, made a suggestion which to me seems very sensible—namely, that there is a common denominator in scleroderma, dermatomyositis, lupus erythematosus, Libman-Sacks disease, and periarteritis nodosa, and that this denominator is probably arterial disease.

I might say that while my impression of this case today seems best to fit into lupus erythematosus disseminata, the overlapping of the diseases discussed makes it necessary to consider the others as distinct possibilities.

### Pathologic Report

The patient was a woman of 40 who was admitted for the first time in 1942 for headaches and nervousness of one year's duration. She was found to have hypertension; the urine was well concentrated and contained albumin, granu-

[Continued from page 2268]

lar casts, red blood cells, and white blood cells. An electrocardiogram showed myocardial damage. The patient had also nodules in the subcutis of the palm, covered by erythematous skin. During her stay at the hospital she showed a maculopapular rash of the palms and chest, associated with fever, leukocytosis, and enlargement of the spleen and the lymph nodes. All these symptoms subsided spontaneously.

Her second admission was two months later, for recurrence of all her symptoms, including the rash. A nodule developed in the calf. After biopsy of the nodule there was a diagnosis of granulomatous inflammation, possibly Bazin's disease. Muscle biopsy showed no pathologic changes. The symptoms, except for the hypertension, disappeared spontaneously. The third admission was nine days after the patient's discharge from the hospital, for beginning gangrene

of the left foot, which was amputated three months later and showed chronic myositis. In the eye-grounds exudates and hemorrhages were found. The patient's final admission was one year later for exacerbation of her initial symptoms. In addition to the hypertension, urinary findings and eyeground changes, she had severe anemia, nonprotein nitrogen of 112 mg. per cent, and developed pericarditis and evidence of heart failure.

The patient died after several attacks of generalized convulsions. At autopsy generalized arteriolar sclerosis and focal arteriolar necrosis were found, with thrombosis of the small vessels and infarcts of the liver. There was organizing pericarditis and evidence of heart failure. Except for a small tubercle in the myocardium, no evidence of active tuberculosis was found. Due to limitations in the autopsy permit, the brain was not examined.

#### CANCER FOUNDATION SEEKS FUNDS

On September 4 the National Foundation for the Care of the Advanced Cancer Patients, Inc., opened a campaign to raise \$1,800,000 to provide beds and care in established institutions at low cost for incurable cancer patients. The campaign will be carried out under the direction of the Foundation's executive committee, consisting of Julius J. Perlmutter, president; Dr. Frank E. Adair, president of the American Society for the Control of Cancer; Dr. Roscoe R. Spencer, director of the National Cancer Institute, Bethesda, Maryland; John W. Wingate, of New York University; Morris M. Bernstein, treasurer; Morton Morrison, secretary of the foundation, and Mrs. Francis J. Rigney, commander of the Metropolitan area of the Women's Field Army of the New York City Cancer Committee.

#### INTERNATIONAL MEDICAL ASSEMBLY

The twenty-ninth annual International Medical Assembly of the Inter-State Association of Medical Associations of North America was held in Chicago on October 17, 18, 19, and 20, 1944, at the Palmer House.

The following New York State doctors were on the program: Dr. John J. Moorhead, consulting surgeon, New York Post-Graduate Medical School and Hospital, and Reconstruction Hospital; and Dr. John F. Erdmann, attending surgeon, New York Post-Graduate Medical School and Hospital.

Dr. Erdmann was also president of a clinic; Dr. Walter W. Palmer, of New York City, was a member of the committee on medical research and advancement; and Dr. Russell L. Cecil, of New York City, was on the program committee.

#### PENICILLIN MAY MASK SYPHILIS SYMPTOMS

Penicillin used to treat gonorrhea may mask or hide the symptoms of syphilis in patients who have both diseases, physicians of the U.S. Public Health Service, Federal Security Agency, reported.

However, the possibility of overlooking syphilis symptoms in gonorrhea patients treated with penicillin can be avoided if special microscopic tests are made before penicillin is used, and if blood tests are made after penicillin treatment has been completed, it was reported by Dr. C. J. Van Slyke, of the Public Health Service Venereal Disease Research Laboratory, Staten Island, and Dr. S. Steinberg, of the U.S. Marine Hospital, New York City.

The masking effect of penicillin on syphilis symptoms is due to the fact that the relatively small amounts of penicillin required to cure gonor-

rhea are sufficient to cause disappearance of the spirochete germs of syphilis from syphilis sores, although not sufficient actually to cure syphilis. When serum from the sores is examined under a special microscope after penicillin has been used, the spirochete germs will not be seen, and the examining doctor may be misled to conclude that the patient was not infected with syphilis. Making the microscope examination before treatment with penicillin prevents this possible error, the Public Health Service workers said.

A blood test for syphilis some time after the treatment of gonorrhea has been completed is advisable because blood tests do not always reveal very new syphilis infections immediately after they have been acquired, it was pointed out.

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M. D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M. D., and Charles D. Post, M. D.*

## Endocrines in Gynecology

THE Medical Society of the County of Broome met on October 10 at 8:30 P.M. in the auditorium at Binghamton City Hospital for postgraduate instruction in gynecology. A lecture, "The Practical

Applications of Endocrines in Gynecology," was delivered by Dr. Morris Aaron Goldberger, associate gynecologist at Mount Sinai Hospital, New York City.

## Diseases of the Skin

POSTGRADUATE instruction in general medicine was given to the Medical Society of the County of Seneca on October 12 at 2:00 P.M. at the Willard State Hospital in Willard.

The lecture was entitled "Common Diseases of

the Skin," illustrated with color photography, and was delivered by Dr. Leon H. Griggs, associate professor of clinical medicine (dermatology and syphilology) at Syracuse University College of Medicine.

## "Penicillin Therapy"

POSTGRADUATE instruction in penicillin therapy was given before the Medical Society of the County of Herkimer on October 10 at 5:00 P.M., at the Mohawk Valley Club. The speaker was Dr. Frank L. Meleney, associate professor of clinical

surgery at the College of Physicians and Surgeons, Columbia University.

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

## Tropical Medicine

THE medical staff of Memorial Hospital of Greene County met on September 28 at 9:00 P.M. at Memorial Hospital, Catskill, for postgraduate instruction. Dr. Barton F. Hauenstein, assistant professor of medicine at the University of Buffalo

School of Medicine, spoke on "Present and Postwar Importance of Malaria and the Dysenteries."

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

---

## NEW APPOINTMENTS MADE IN TUBERCULOSIS FIELD

Recent appointments of personnel have been made through the employment service of the State Charities Aid Association's State Committee on Tuberculosis and Public Health.

Miss Amy E. Rogers, Englewood, New Jersey, was appointed executive secretary of the Cattaraugus County Tuberculosis and Public Health Association, Inc., August 1. She is a graduate of the Central School of Hygiene and Physical Education, now the Department of Physical Education, Russell Sage College, Troy. She received a B.S. degree from the School of Education, New York University, last June. Since 1937, she had served as director of physical education for nurses at the Jersey City Medical Center, School of Nurses.

Miss Frances L. Kraft, field demonstrator on the State Committee's staff, who served as acting executive secretary of the Cattaraugus Association for the past year, has received a similar appointment for the next four months by the S.C.A.A.'s Genesee County Christmas Seal Committee, Batavia, preparatory

to the employment of an executive secretary by that Committee in January. Miss Kraft was formerly associate professor of biology, Wells College, Aurora, New York.

Miss Catharine Hyde, who was graduated from Vassar College in 1928, has joined the State Committee staff as a trainee. Miss Hyde has had extensive high school teaching experience in social studies, English, and mathematics.

Miss Caroline J. Lum, Barker, New York, joined the State Committee's staff on October 9 as a trainee preparatory to becoming executive secretary of the Wayne County Tuberculosis and Public Health Association on November 1. Miss Lum is a graduate of Buffalo State Teachers College in home economics and received additional training in nutrition at the State College of Home Economics, Cornell University. In recent years she has been associated with the Farm Security Administration and the State Emergency Food Commission.—S.C.A.A. News, September, 1944

## Annual Conference of State Secretaries and Editors

THE Annual Conference of Secretaries of Constituent State Medical Associations and Editors of State Medical Journals will be held in Chicago at the offices of the American Medical Association on Friday and Saturday, November 17 and 18. Two sessions of the conference will be held on Friday, November 17, the first at 10:00 A.M. and the second on the afternoon of that day. On the evening of November 17 a program given over to the discussion of topics of particular interest to editors of the journals of constituent state medical associations will be presented at the Palmer House. The concluding session of the conference will be held at the offices of the Association on the morning of Saturday, November 18.

While these annual conferences have each year

been attended by nearly all of the secretaries of constituent state medical associations and editors of medical journals of those associations, there has been a constantly increasing attendance of other officers of constituent state medical associations and officers of component county and district medical societies, and of late years a very considerable number of members who do not occupy official positions have been present. The members of all those groups will be cordially welcome at the November conference.

All who expect to attend the conference this year are especially urged to make necessary arrangements for hotel accommodations and railroad transportation at the earliest possible time.—*J.A.M.A., Sept. 23, 1944*

## Plans Outlined for Medical Training After War

OUTLINING the educational facilities required after the war for returning medical officers, Victor Johnson, M.D., and F. H. Arestad, M.D., secretary and assistant secretary, respectively, of the Council on Medical Education and Hospitals of the American Medical Association, in a report in the *Journal of the Association* for September 23 present recommendations to the hospitals and medical schools of the country for meeting the educational challenge of the postwar period.

Their report is based on studies by the Council and returns on questionnaires sent to medical officers by the Committee on Postwar Medical Service and analyzed by Lieut. Col. Harold C. Lueth, (MC), Surgeon General's Liaison Officer in the headquarters of the Association.

"Meeting the requirements of returning medical officers for additional training," Drs. Johnson and Arestad say, "is a serious responsibility which will require the continued joint efforts of the Committee on Postwar Medical Service, the Council on Medical Education and Hospitals, the Surgeons General of the Army, Navy, and Public Health Service, hospitals approved for internships and residencies, the American boards in the medical specialties, medical schools, state licensing boards, the Veterans Administration, foundations, county and state medical societies, and every institution capable of providing advanced training to physicians.

"On these physicians rests a large share of the responsibility for the quality of medical care to be provided the nation in the decades following the war. Many entered the services after an abbreviated internship. Others recognize the need for further education to equip themselves to return to their practices or to new locations in which they

an editorial in the same issue, port, says:

uggests ways in which efforts may meet the need. Returns on the ent to all medical officers are now

numbers which clearly reflect the st in continuation training. Analy-

random sample has already been data are indispensable for effec-

medical officers will want house-

officer training of six months or more. Since demobilization will probably extend over some time, the number of additional places required will probably approximate 5,000 during the first year. Apparently most expansion will be required in otolaryngology, surgery, obstetrics and gynecology, and ophthalmology, which may need to double their facilities. Expansions of 50 to 70 per cent seem to be indicated in urology, internal medicine, orthopaedic surgery, and pediatrics.

"Somewhat fewer officers are likely to seek shorter courses; about 9,000 officers will seek full-time training of one to six months' duration. In 1943-1944 there were nearly 27,000 physicians enrolled in such courses. However, over 90 per cent of these were in short courses of about a month. Apparently more than 90 per cent of those desiring review or refresher courses will seek training in somewhat longer courses of two to six months' duration. Many more courses of that duration will be required.

"In the light of the figures given, all institutions which can contribute to meeting the need are obligated to review their resources and prepare estimates of the additional facilities they can provide, to facilitate the achievement of the program outlined. . . .

"With continuing operation of the . . . [various agencies and groups concerned] there is every reason to expect that the needs will be met. Information now being collected from all educational institutions will be made available in the near future. . . ."

In summarizing their report, Drs. Johnson and Arestad say that the Council on Medical Education and Hospitals recommends, in order to meet the educational challenge of the postwar period, that:

Every hospital approved by the Council for internships should review its present and potential facilities and be prepared on request to submit to the Council estimates of the additional physicians it can accommodate as house officers in general medical training without jeopardizing high educational standards.

Every residency and fellowship hospital approved by the Council and acceptable to the various American boards should be prepared to submit to the Council and to the respective boards estimates of the

AS THE FINAL processing step, Lanteen Jelly is filtered through six fine stainless steel screens, each of 200 mesh—an example of the painstaking control of purity and uniformity maintained throughout production. Control of the efficacy of its products, by latest scientific means, is the constant aim of Lanteen Medical Laboratories.

Lanteen Flat Spring Mensinga Type Diaphragm is available *on the prescription of a physician.*

Since patients are not mechanically minded, simplicity and ease of handling are prime requisites for continued use. Lanteen Lilac flat spring diaphragm is extremely simple to place—it is collapsible in one plane only. No inserter required.

L A N T E E N

[Continued from page 2274]

additional physicians it can accommodate as house officers in already approved residencies.

Every internship hospital not now approved by the Council for residencies should be prepared to report on such facilities it may possess as may warrant consideration for approval of residencies, particularly in those specialties requiring most expansion.

Every approved residency hospital which has not yet developed its educational programs to full capacity should consider the organization of educational residencies in specialties not yet approved by the Council.

There should be developed in approved hospitals graduate externships to provide training of short duration to discharged officers not housed at the hospital but engaged in full-time hospital work.

Medical schools, societies, and foundations should

plan especially to meet the probable demands for full-time review and refresher courses of two to six months' duration.

Appropriate work in the basic medical sciences should be included in all postwar house-officer training programs.

Consistent with national security and postwar military needs, teachers who are medical officers should be demobilized for the training of discharged officers before the prospective students.

Although modification of present estimates may be required when further questionnaires have been returned from medical officers, plans by all medical educational institutions for expanded postwar facilities should commence at once.

Full use should be made of the period between the surrender of Germany and that of Japan to provide educational training for as many officers as possible while still retained on active service.

### Conference to Speed Research in Fight on Cancer

**I**MPRESSED by the benefit they had derived by discussing the cancer problem as a group, and convinced that cancer research in widely separated fields would make more rapid progress if it were planned and organized, the forty scientists who attended sessions held by the Conference on Parental Influence in Cancer, held at Bar Harbor, Maine, September 21-25, adopted a procedure which resembles a charter with fourteen points.

In the preamble a sharp distinction was drawn between influences which may be hereditary and therefore may run in families and those which are definitely not hereditary, such as chemicals, hormones, and human milk. These influences need much further study.

The conference decided that "it is imperative to extend our knowledge of the interaction of these two major influences in man" and that it is desirable to include in the study all kinds of benign or malignant tumors "as well as conditions leading to either of these."

The conference agreed that it is better not to define cancer scientifically because pathologists are not always certain at what point a tumor becomes a cancer. For practical purposes it was decided, as one of the fourteen points, to accept "the diagnosis made by competent pathologists on the basis of microscopic examinations."

Clinical findings without a microscopic examination would be accepted only in the case of families that seem to be of a cancerous strain.

Because of the lack of trained specialists the research is limited to cancer of the breast and the female sex organs.

Another of the fourteen points calls for study "of possible hormonal influences on breast cancer with special reference to ovary, adrenal, and pituitary glands," of microscopic examinations of the breast much more extensive than those usually made, of autopsies made on women who have not died of breast cancer, and of "the possible presence of a milk influence in women." Such an influence has been established in cancerous strains of mice. A similar procedure is to be followed in studying cancer of the female sex organs.

To study apparently hereditary cancer, designated general and cancer hospitals will be asked to supply records, of the kind desired, which means, "detailed data regarding all members of the family continued throughout life." Each hospital is to set up a control study group, selected so as to supply entirely comparable information.

Still another of the fourteen points calls for the creation of "a central agency of national scope to coordinate and guide the study" of cancer of the types immediately under consideration. "The attention of the medical profession and of health authorities is to be called to the need for gathering reliable data regarding the incidence of various forms of cancer by special survey or preferably by making cancer a reportable disease," it was stated.

The final point dealt with the correlation of the findings of experimenters with laboratory animals and of scientists who are studying human cancer.

A partial list of those invited to attend the Conference on Parental Influence on the Incidence of Human Cancer at Bar Harbor included Dr. F. E. Adair, president of the American Cancer Society and head of the Breast Cancer Service at the Memorial Hospital, New York; Dr. H. B. Andervont, principal biologist at the National Cancer Institute, Bethesda, Maryland; Howard Blakeslee, science writer of the Associated Press and former Pulitzer Prize winner; Dr. F. Blank, director of the Survey of Constitution in Cancer, Bureau of Human Heredity, London, England; Dr. W. Ray Bryan, biologist at the National Cancer Institute; Dr. D. R. Charles, zoologist at the University of Rochester; Dr. Leon Cole, professor of genetics at the University of Wisconsin; Robert Cook, editor of the *Journal of Heredity*, Washington, D.C.; Dr. William Cramer, research associate at the Barnard Hospital, St. Louis, Missouri; Dr. F. Duran-Reynals, associate professor of bacteriology, Yale University; Dr. H. S. N. Greene, associate professor of pathology, Yale University; Dr. W. E. Heston, geneticist at the National Cancer Institute; Dr. Waldemar Kaempfert, science editor of the *New York Times*; Dr. M. L. Levin, assistant director of the Division of Cancer Control of the New York State Department of Health; Dr. Herbert Lombard, director of the Division of Adult Hygiene of the Massachusetts Department of Health; Dr. Clara J. Lynch, associate of the Rockefeller Institute, New York; Dr. Madge T. Macklin, assistant professor of histology and embryology, University of Western Ontario, London, Ontario; Dr. R. G. Meader, assistant professor of anatomy and assistant director of the Jane Coffin Childs Memorial Fund, Yale University; Dr. Douglas Murphy, professor of gynecology at the University of Pennsylvania; Dr. James B. Murphy, member in charge of cancer research at the Rockefeller Institute; Dr. C. P. Oliver, director of the

## County News

### Albany County

A meeting of the county society was held on September 27 at 8:30 p.m. in the auditorium of the Albany College of Pharmacy.

Following a short business meeting the vice-president of the county society, Dr. Arthur J. Wallingford, gave the scientific address—"Ascites in Gynecology." Dr. Wallingford is professor of gynecology and director of the Department of Gynecology and Obstetrics at Albany Medical College.

An address by Dr. Arthur J. Wallingford was the feature of the first regional conference on cancer held in Albany on September 20, under the direction of the Women's Field Army of the American Cancer Society.\*

### Dutchess County

A regular meeting of the county society was held at the Wassaic State School, Wassaic, New York, Wednesday, September 20, at the invitation of the director, Dr. Raymond G. Wearne.

Dinner was served at 7:00 p.m. The Scientific program was an address, "Recent Advances in the Diagnosis and Treatment of Chest Diseases," by Dr. George Guthman Ornstein, director of medicine at Seaview Hospital, Staten Island, New York, director of tuberculosis at Metropolitan Hospital, New York City, consultant, Horton Memorial Hospital, Middletown, New York, and clinical professor of medicine, New York Post-Graduate Medical School.

A special meeting of the county society was called on August 30 at the Nurses' Home at Vassar Brothers Hospital in Poughkeepsie to discuss poliomyelitis.

Dr. James L. Wilson, professor of pediatrics and director of the Department of Pediatrics at the New York University College of Medicine, spoke on "Clinical Features—Pathology, Diagnosis, and General Treatment." "Physical Therapy in the Acute and Convalescent Stages" was the title of an address by Dr. Philip M. Stimson, associate professor of clinical pediatrics at Cornell University Medical College. A paper on the "Epidemiology of Poliomyelitis" was read by Dr. James E. Perkins, Director of the Division of Communicable Diseases of the New York State Department of Health.

### Erie County

A stated meeting of the county society will be held on Tuesday, October 24, in the Georgian Room of the Hotel Statler in Buffalo.

The manual, "Diagnostic Standards and Classification of Tuberculosis," is being offered to physicians by the Buffalo and Erie County Tuberculosis Association.

This manual covers the pathogenic development of pulmonary tuberculosis including the primary phase, reinfection phase, hematogenous disseminations, and the healing or repair processes. Since correlation of all findings in a case of tuberculosis on a sound conception of pathogenesis is necessary in clinical practice, the manual illustrates some of these correlations.

Differential diagnosis of pulmonary disease is summarized as well as the various stages of pulmonary tuberculosis. Definitions regarding extent of pulmonary lesions, severity of symptoms, clinical status, etc., are given.

### Jefferson County

Dr. George E. Sylvester, of Black River, one of the oldest practicing physicians in northern New York, observed his eightieth birthday on September 5. He has conducted a medical practice in Black River continuously for fifty-five years.

No special celebration was held and the doctor continued a daily routine he has followed practically ever since he entered the medical profession. He enjoys good health and still maintains a stiff daily schedule of from fourteen to sixteen hours.

Dr. Sylvester is a past president of the Jefferson County Medical Society. He has served as village health officer and health officer of the town of Rutland for many years.

Always active in community functions and affairs, he was president of the board of education at the time that a large frame school house was constructed about 1899 in Black River.\*

### Kings County

For six consecutive years postgraduate courses in various aspects of pathology have been offered at the Israel Zion Hospital, Brooklyn. For the fall season of 1944, beginning on October 17, the course selected will be "Pathology of Internal Medicine."

This course is designed to familiarize the internist as well as the general practitioner with the fundamentals of gross and microscopic pathology of internal medicine. Great stress is laid on gross pathologic diagnosis of tissues and organs.

This course is conducted by Dr. Jacob M. Ravid under the auspices of the Joint Committee on Postgraduate Education of the Long Island College of Medicine, the Medical Society of the County of Kings, and the Academy of Medicine of Brooklyn.

Further information may be obtained from the Registrar, 1313 Bedford Avenue, Brooklyn, New York.

[Continued from page 2278]

to the 1944 Deficit Fund for county physicians in the armed forces was \$12,376.50.

### Monroe County

The county society inaugurated its 1944-1945 radio broadcast program at 1:30 P.M. on September 9, over WHAM, to start the fourteenth season the society has been on the air. The first subject was "Fifth Freedom—Free Choice of Physician."

The society proclaims its broadcast to be "the oldest continually produced medical broadcast in the world." The September program was the 552nd in the series, which will continue until June 29, 1945.

A new program of summer broadcasts on child health was inaugurated this season. The ten broadcasts were arranged by the Child Welfare Committee, of which Dr. Herbert C. Soule is chairman.\*

### New York County

One hundred and seventy-two students of the College of Physicians and Surgeons and the School of Dental and Oral Surgery of Columbia University were graduated at special ceremonies on September 28 at 11:00 A.M. in the McMillin Academic Theatre, Broadway and 116th Street.

Dr. Willard C. Rappleye, dean of the College of Physicians and Surgeons of Columbia University, spoke at a dinner for the senior class of the college, whose 124 members received their degrees. The dinner was given by the college's alumni association at the University Club, Fifth Avenue and Fifty-fourth Street.

The other speakers were Comdr. Gordon Bruce, who served two years on Guadalcanal with the Marine Corps, and John Kieran, newspaper columnist, whose son, James, is a member of the graduating class.\*

Dr. Marie Warner delivered a lecture entitled "Sperm Viability in the Female Genital Tract" on Thursday, September 14, 1944, before the meeting of the American Association for the Advancement of Science held at Cleveland, Ohio.

Thomas P. Fleming, M.S., librarian of the Columbia University College of Physicians and Surgeons, has been appointed assistant director of the libraries of the university.

Dr. George T. Pack was recently decorated by the president of Chile with the title of Grand Officer of the Order of Merit.

Frank S. Lloyd, Washington, D.C., executive officer of the Committee on Physical Fitness of the Federal Security Agency, has been appointed chairman of the department of hygiene of the College of the City of New York, succeeding Frederic A. Woll, Ph.D., who retired because of age on August 31.

Ivan C. Hall, Ph.D., since 1942 director of the central laboratory, contaminated wound project, subcommittee of surgical infections, National Research Council, formerly professor and head of

the department of bacteriology and public health in the University of Colorado School of Medicine, Denver, has been appointed professor and chairman of the department of bacteriology at the New York Medical College, Flower and Fifth Avenue Hospitals. He will succeed Laura Florence, Ph.D., who retired in September.

Dr. Otto Loewi, research professor in pharmacology at New York University College of Medicine, has been awarded the Cameron Prize in Practical Therapeutics of the University of Edinburgh in recognition of "his fundamental work on the chemical transmission of the nervous impulse," *Science* reports.

Dr. Joseph Jordan Eller will address the Waterbury, Connecticut, Medical Society at the Waterbury Club on November 9 at 8:30 P.M. The subject will be "Tumors of the Skin" (benign and malignant), with lantern slide demonstration.

Applications are now being accepted for the Lewis Cass Ledyard, Jr., Fellowship by the Society of the New York Hospital. Three thousand dollars will be available as a stipend to an investigator in the fields of medicine and surgery or in any closely related field and about \$1,000 for supplies or expenses of the research. Preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. Applications should be received by the Committee of the Lewis Cass Ledyard, Jr., Fellowship not later than December 15. It is expected that the award will be made by March 15, 1945. Additional information may be obtained from Dr. Eugene F. Du Bois, chairman of the committee, Society of the New York Hospital, 525 East 68th Street. The fellowship was established in 1939 by a gift from Mrs. Ruth E. Ledyard in memory of her late husband, Lewis Cass Ledyard, Jr., a governor of the New York Hospital.

Harlem soon will have its own "little red door" cancer information service at 2007 Seventh Avenue, where space has been leased by the New York City Cancer Committee. The office also will serve as Harlem division headquarters of the Women's Field Army of the American Cancer Society, according to Mrs. Francis J. Rigney, commander in Manhattan. Dr. John E. Moseley and Dr. Farrow Allen are cochairmen of the Harlem division.

Drs. Edith M. Quimby and Beverly C. Smith, of Columbia University College of Physicians and Surgeons, report in *Science*, August 25, on the use of radioactive sodium as an aid in the diagnosis of diseases of the circulation. The radioactive sodium also aids in the making of the prognosis and in evaluating the effect of treatment. It is made by bombarding sodium metaborate with deuterons in the cyclotron.

Circulation time is measured with this substance by the injection of a sterile solution into the arm; when blood containing the sodium reaches the foot a Geiger counter held against the sole clicks.

## PRE-NATAL INFLUENCE

Psychologists report startling recent results in baby-influencing

Small doses of electricity injected in the uterus of female rats produced a litter with superior intelligence—but a double potency had the opposite effect

Baby rats born and raised in cold rooms were smarter than those in hot rooms

Male and female rats given small doses of pituitary extract produced smart offspring

Rats were very fertile when they lived in a cage enclosed by a yellow light filter. Behind a blue filter, they had no young at all

## MORE AMERICAN INGENUITY

Dr H L Ansbacher of Brown University, made the point that German military psychology approached its problem clinically

This is good when it can be carried out. American military psychology considered the approach impractical for an army of the size we decided to raise. Hence we concentrated on standardized tests with ratings made by trained observers, commanding officers under whom candidates served, or special boards

German experience seems to prove that the judgment of American psychologists was sound

## THE MAPLES INC., ROCKVILLE CENTRE, L. I.

[Continued from page 2280]

It has been suggested that the substance also be used in a study of the acute type of frostbite suffered by aviators in short exposures to low temperatures, as well as of immersion foot.

The New York Diabetes Association announced on August 23 that it had taken title to the former Golden Rule Inn property on Mirror Lake four miles below Kingston, New York, and will convert the buildings into a camp for poor diabetic children of greater New York. Dr. George E. Anderson, Brooklyn president of the association, estimated that \$10,000 would be needed to convert the buildings to meet the requirements of a diabetic children's camp, according to the *New York Times*.

#### Ontario County

"Hysterectomy" was the subject of a paper by Dr. Harry M. Smith given on September 1 before members of the Canandaigua Medical Society at a meeting at the Yacht Club. Dr. Smith also was host, dinner being served to nine, including Dr. Frederick C. Robbins and Dr. Ludwig Mayer, guests.

Dr. C. Harvey Jewett reported on the poliomyelitis conference held in Rochester under the auspices of area medical societies, including the Ontario County group, and the State Medical Society and State Health Department.

The October meeting took place on October 6, with Dr. A. W. Armstrong as host and Dr. Margaret T. Ross as reader.\*

#### Queens County

The annual joint meeting of the county society and the Queensboro Tuberculosis and Health Association was held on September 28.

The meeting was opened with remarks by Dr. James R. Reuling, Jr., president of the Queensboro Tuberculosis and Health Association. An address entitled "Medical Observations in the Middle East and Africa" was delivered by Rear Admiral Charles S. Stephenson, (MC), USN. The discussion leader was Dr. Ernest L. Stebbins, New York City Commissioner of Health.

The Friday Afternoon Lecture on October 27 will be "The Treatment of Infections of the Hand," by Dr. David Goldblatt, assistant professor of surgery, Columbia University.

#### Schenectady County

The regular monthly meeting of the county society was held at the Ellis Hospital Library, Schenectady, on October 3 at 8:30 p.m. Dr. George W. Thorn, Hersey Professor of Medicine at Harvard Medical School, spoke on "Diagnosis and Treatment of Gout."

#### Steuben County

The Steuben County Bar Association and the Medical Society of the County of Steuben held a joint luncheon meeting at the Hotel Sherwood, Hornell, on September 11. The program was devoted to the medical and legal problems in paternity cases.

Dr. Philip Levine, director of the Biological Division, Blood-Testing Laboratory of the Ortho Research Foundation, Linden, New Jersey, spoke on the "Medicolegal Consideration of Blood Groups in Paternity Cases." Dr. Levine is known internationally as one of the foremost authorities on blood groups.

Attorney W. Earle Costello, of Corning, spoke on the "Legal Aspects of Paternity Cases."\*

#### Westchester County

Boyden Roseberry, formerly director of the medical department of the Children's Aid Society of New York, has succeeded James E. Bryan as executive secretary of the Westchester County Medical Society.

Mr. Roseberry began his professional career as a school-teacher in Singapore. In his work with the Children's Aid Society he supervised their two convalescent homes in Chappaqua and Valhalla, and was a member of the Westchester Hospital Association.

Graduated from Vanderbilt University in 1930, he took postgraduate work at Columbia University.

## New York Hospital Fund Starts Annual Campaign

WITH \$1,554,931.56 as the immediate need, and with the sphere of its service being expanded to meet postwar problems and demands, the United Hospital Fund of New York opened its sixty-sixth annual campaign on September 25, at a dinner in the Hotel Commodore. The appeal will continue through November 4.

The participating members of the city-wide appeal are seventy-seven voluntary hospitals, women's auxiliaries, medical social service committees, and the Visiting Nurse Association of Brooklyn.

Four thousand volunteer workers are doing the soliciting under the direction of James S. Adams, general chairman of the campaign. A small booklet entitled "Tomorrow One of These Seventy-seven Hospitals May Be Your Friend in Need" is being used by the campaign workers to carry to the people of New York City the story of the volunteer hospitals' services.

The booklet reveals that more than half of the hospital care in this city is provided by the voluntary hospitals, and about half of that care is provided free or at less than cost.

Last year, the booklet points out, 3,404,799 patient-days of free or part-pay care were given in the seventy-seven voluntary hospitals participating in the United Hospital appeal. In the outpatient departments 3,373,704 visits were made.

The money raised annually by the United Hospital Fund, together with the money contributed to the voluntary hospitals that are members of that Fund by employee groups, firms, and corporations through

the Greater New York Fund, helps to assure hospital care when needed for all New Yorkers, regardless of race, creed, or ability to pay, the booklet declares.

Speaking of the contribution made to the war effort of the nation, the booklet says, "War has taken from our voluntary hospitals doctors, nurses, technicians, medical social workers, and other essential personnel, but those left at home are carrying on, meeting wartime rehabilitation problems, and doubling up on work to serve in case of sickness or accident."

To a considerable extent the problem of the loss of personnel has been solved by the service of some 10,000 home-front volunteers. The problem of increased cost due to war was partially met in 1943 by an encouraging increase in the amount and number of voluntary contributions."

The total income of the seventy-seven participating hospitals is reported as \$49,759,423.35, and the total cost of services provided as \$51,314,354.91. Therefore, the booklet states, the amount to be sought from the public this year amounts to \$1,554,931.56.

Roy E. Larsen, president of the United Hospital Fund, opened the program at the dinner. The guest speaker was Lt. John Mason Brown, USNR, who recently returned to this country after taking part in the invasions of Italy and France.

More than a thousand of the persons who have volunteered as campaign workers attended the dinner.

### WHY DO WE SMOKE?

An article in the *Ladies' Home Journal* asks the question "How about smoking—is it a character habit?"

It is, it, too, is not because of the taste of the smoke but because of the emotional desire for the stimulation of lips and mouth. The basis for smoking appears early in life in the form of a lollipop, chewing gum and thumb sucking activities. This mouth-centered emotion stays with many through life and is shown by such adult habits as smoking, kissing, nail biting, be-

to conquer emotions, the habit, mouth centered make up which starts the habit and makes it strong. That is why people who break off smoking are likely to find themselves biting their nails, over eating and gaining weight, biting their lips like the mental patients just described, or—believe it or not—going on a kissing spree!"

# Multi-vitamins in surgery and obstetrics . . .

## Lederle VI-MAGNA LENTABS EIGHT VITAMINS

**A**LERT SURGEONS have been quick to appreciate the great usefulness of preoperative and postoperative multi-vitamin administration. Patients who reach the operating table in an excellent state of nutrition and in favorable mental condition react, in general, better to surgery than those who have previously received an inadequate diet.

### Multi-vitamin administration is useful in—

Preoperative and Postoperative Care  
Wound Healing  
Surgical Vomiting  
Jejunal Fistula Enterostomy and Allied Operations  
Pregnancy and Lactation

### VI-MAGNA LENTABS Lederle

*Each LENTAB supplies a full daily supplement of essential vitamins:*

Vitamin A.....	5,000 U.S.P. XII Units
Vitamin D.....	500 U.S.P. XII Units
Ascorbic Acid (C).....	30 mg.
Thiamine HCL (B <sub>1</sub> ).....	3 mg.
Riboflavin (B <sub>2</sub> ).....	2 mg.
Niacinamide.....	20 mg.
Calcium Pantothenate.....	10 mg.
Pyridoxine HCL (B <sub>6</sub> ).....	0.2 mg.

VI-MAGNA LENTABS are thin, easily swallowed, gelatin-coated tablets. The fat-soluble vitamins are emulsified in a gelatin matrix containing the water-soluble vitamins. This improved structure releases the vitamins slowly so that after-taste is abolished.

PACKAGES: Bottles of 50, 100 and 1000 Lentabs.

VITAMIN DEFICIENCY IS USUALLY  
MULTI-VITAMIN INSUFFICIENCY

# Not Lances, but a

# Lancet

HE's a man of battle. He doesn't charge in with lance atilt—or its modern equivalent the bayonet, the Tommy gun, the Garand—but he's fighting for life, all the same. The lives of other men... and constantly at the risk of his own in those advanced dressing stations and field hospitals. Bombs lash down... shells burst... but he stays at his post.

Once in a while he has a moment to himself. A moment of relaxation... time for a cigarette... time for a Camel. With men in all the services, Camel is the favorite according to actual sales records.

### as a Valuable Aid Before and After BILIARY TRACT SURGERY

When Decholin (dehydrocholic acid) or its sodium salt (intravenous) is given prior to surgery, the copious outpouring of thin liver-bile, secreted under increased pressure, makes bile ducts and gallbladder stand out prominently at operation, facilitating identification and manipulation.

Postoperatively, when external drainage is not employed Decholin tablets, usually tolerated after 48 or 72 hours, improve common duct drainage, aid in the removal of debris, reduce the discomfort. When drainage is used, Decholin hastens return of bile secretion, aids in disposing of inspissated bile, gravel, small stones overlooked at surgery. Contra-indicated only in complete biliary obstruction.

**MARINOL**  
(IMPROVED FORMULA)

MARINOL (IMPROVED FORMULA) is an homogenized emulsion of cod liver oil and vegetable oils fortified with fish liver oils of high vitamin A potency to which has been added pure vitamin D<sub>3</sub>.

**OUTSTANDING PROPERTIES**

**PALATABILITY:** The desirable properties of the fish liver oils have been retained without the disagreeable taste and odor.

**HOMOGENIZATION:** This assures a uniform and stable product that permits of easy miscibility with milk, special formulae, fruit or vegetable juices, or with water.

**HIGH VITAMIN POTENCY:** 5,000 U.S.P. units of vitamin A and 500 U.S.P. units of Vitamin D<sub>3</sub> supply the daily minimum requirements (FDA) in one teaspoonful.

**LOW COST:** A single teaspoonful daily is a prophylactic dose

**FOOD VALUE:** Fish liver and vegetable oils supply another desirable property—that of caloric value

**EASY ADMINISTRATION** is possible because of unusual potency of small dose.

**CONSUMER PRICE:** Bottle of 6 fl. oz. 85 cents. Bottle of 12 fl. oz. \$1.50 (M.P.R. 392). **HOW SUPPLIED:** Bottles of 6 fl. oz. and 12 fl. oz.

**FAIRCHILD BROTHERS AND FOSTER**  
70-76 LAIGHT ST., NEW YORK 13, N. Y.

# BELBARB

## AN

# Excellent

## SEDATIVE

and

## HYPNOTIC

The potentiation of the central action of phenobarbital by the belladonna alkaloids (Friedberg, Arch. f. exp. P. & P. CLX, 276) renders possible attainment of desired effects with relatively small doses, thus avoiding "hang over" and other unpleasant side-actions. In contrast to galenical preparations of belladonna, such as the tincture, *Belbarb has always the same proportion of the alkaloids.*

**Indications:** Neuroses, migraine, functional digestive and circulatory disturbances, vomiting of pregnancy, menopausal disturbances, hypertension, etc.

**Formula:** Each tablet contains  $\frac{1}{4}$  grain phenobarbital and the three chief alkaloids, equivalent approximately to 8 minims of tincture of belladonna.

Belbarb No. 2 has the same alkaloidal content but  $\frac{1}{2}$  grain phenobarbital per tablet.

# HESODATE *Brewer*

The ORIGINAL ENTERIC-COATED TABLET  
OF THEOBROMINE SODIUM ACETATE

*to control frequency and severity of  
attacks in* **CARDIOVASCULAR AND  
RENAL DISEASES** *and to prevent EDEMA*

Clinical experience and studies have proven the value of Theobromine Sodium Acetate in certain Cardiovascular and Renal Diseases. In Angina Pectoris, used adequately, it permits more work by the individual without developing precordial pain or distress. As one of the most effective Xanthine Vasodilators it helps increase the available blood supply to the heart and kidneys to increase the efficiency of these organs.

It has also been found an effective aid in treating and preventing Edema of Cardiac or Renal origin. The enteric coating (especially developed for Thesodate) permits larger doses without the drug's contact with the Gastric Mucosa.

AVAILABLE IN  
various potencies with  
or without Phenobarbital.  
Literature on request.

# "Uncooked fats...and Ketochol"

For the physiologic management of bile tract dysfunctions, Ketochol has been designed for use in conjunction with the high-fat diet (butter, cream, etc.).

Ketochol has a hydrocholeretic action, providing a mechanical flushing of the biliary passages, removing the products of inflammation and "biliary stasis."

A combination of the oxidized (keto) forms of ALL FOUR bile acids normally present in human bile—Ketochol increases the bile flow an average of 144%, yet manifests no significant toxic effects systemically or locally.

Available in bottles of 100, 500 and 1000 tablets.

Ketochol is the registered trademark of G. D. Searle & Co.

## BLUNDELL METHOD, 1828

• • • In 1828, James Blundell, using a crude gravitation method, transfused blood directly from man to man.

CRUDE though it was, James Blundell's experiment was a milestone in medical progress. The difficulties of typing and cross-matching, however, pointed to the need for an acceptable blood substitute. Blood plasma was the substitute of choice, and dried plasma has proved especially satisfactory because it is stable and portable, and because it can be kept for as long as five years without refrigeration.

In addition to helping supply the Army and Navy, Sharp & Dohme, under a separate project using blood from professional donors, make available 'LYOVAC' Normal Human Plasma to civil medical practice throughout the Western Hemisphere.

Rapidly restored by the addition of distilled water, 'LYOVAC' Normal Human Plasma may be administered at once, without typing and cross-matching. Each 250-cc. unit contains approximately as much osmotically active protein as 500 cc. of whole blood. Sharp & Dohme, Philadelphia 1, Pa.

A development of Sharp & Dohme Research

**'LYOVAC'**

NORMAL HUMAN PLASMA

# HAVE YOU PATIENTS With Any Of These Conditions?

Spencer Abdominal Supporting Corset shown open revealing inner support. This is a *SEPARATE* section, adjustable to the corset section and the patient's figure by means of flat tapes that emerge on outside of corset.

When you prescribe a Spencer Support you are assured it will meet your specific requirements and the patient's figure needs, *because* it will be individually designed, cut and made for the one patient who is to wear it.

Every Spencer Support is individually designed for the patient of non-elastic material. Hence, the support it provides is constant, and a Spencer can be—and IS—guaranteed NEVER to lose its shape. Spencer Supports have never been made *fit stretch to fit*; they have always been *designed to* to. Why prescribe a support that soon loses its shape and becomes useless before worn out. Spencers are light, flexible, durable, easily laundered.

For service, look in telephone book under "Spencer Corsetiere" or write direct to us.

**When raw, painful throats**

**demand relief**

Pharyngitis and tonsillitis of the "cold" season—as well as post-tonsillectomy throats—are often so painful as to make the patient, particularly the young child, reluctant to swallow any type of nourishment.

A routine relief measure used by thousands of physicians to provide comforting relief, and to hasten recovery is

## *Dillard's* **Aspergum**

Chewing Aspergum accomplishes these desiderata:

1. The acetylsalicylic acid is carried to the very site of pharyngeal inflammation. A copious salivary flow, laden with this effective analgesic, is brought into immediate and prolonged contact with painful irritated areas—providing prompt and gratifying relief.

2. Local spasticity and stiffness are relieved through the gentle muscular stimulation afforded by chewing.

3. The patient is more comfortable, earlier partakes of a suitable diet; convalescence is hastened.

In packages of 16, moisture-proof bottles of 36 and 250 tablets. Ethically promoted—not advertised to the laity. White Laboratories, Inc., Pharmaceutical Manufacturers, Newark 7, N. J.

**A PRODUCT OF WHITE LABORATORIES, INC.**

**N**EW streamlined plastic model CLINITEST *Urine-Sugar Analysis Set*. **A Product of AMES COMPANY, INC., Elkhart, Indiana**

## *In the Management of Severe Third-Degree Burns*

much has been learned through the unfortunate occurrence of the Cocoanut Grove fire at Boston. The numerous reports in the medical press emphasize the need for large amounts of dietary protein of adequate biologic value, given as early as possible.\* Meat is one of man's main sources of protein that can be eaten with relish several times daily in goodly quantities; its proteins are of highest quality, and it contributes to the satisfaction of the greatly increased vitamin requirements as well.

\*"All the patients with ten per cent of surface area, or more, involved in third-degree burns became serious nutritional problems. . . . All patients were started on high protein, high vitamin diets. . . . This diet contained 140 Gm. of protein." (Clowes, G. H. A., Jr.; Lund, C. C., and Levenson, S. M.: The Surface Treatment of Burns, *Ann Surg.* 118:761 [Nov.] 1943.)

"... at least from 200 to 300 grams of protein is needed for replacement alone. One must give the patient as much food as he can take . . . give him a good protein, one that contains all of the essential amino acids" (Elman, R.: *Physiologic Problems of Burns*, *J. Missouri M. A.* 41:1 [Jan.] 1944.)

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

**It fights infection  
while she sleeps**

The striking success of Paredrine-Sulfathiazole Suspension in nasal and sinus infections is largely due to its prolonged bacteriostatic action. When the Suspension is administered on retiring, for example, sulfathiazole can often be observed on infected mucosa the next morning—conclusive evidence that bacteriostasis has persisted all night long.

The fundamental reason for this prolonged bacteriostatic action is the fact that Paredrine-Sulfathiazole Suspension—not a solution, but *a suspension* of free sulfathiazole—covers the nasal mucosa with a fine, even frosting of sulfathiazole, which does not quickly wash away. Yet the Suspension does not cake or clump, and does not interfere with normal ciliary action.

Other outstanding advantages:

1. The Suspension does not irritate or sting, because its pH is slightly acid, and identical with that of normal nasal secretions.
2. The Suspension does not produce such central nervous side effects as insomnia, restlessness and nervousness.

Smith, Kline & French Laboratories, Philadelphia, Pa.

## PAREDRIE-SULFATHIAZOLE SUSPENSION

1 *Prolonged*  
bacteriostasis

2 *Non-stimulating*  
vasoconstriction

3 *Therapeutic*  
pH—5.5 to 6.5

# R Pediforme

## FOOTWEAR

## SHOES AS THERAPEUTIC AGENTS

No doctor can ignore that shoe therapy is a major factor in the treatment of many foot disorders. In some cases, however, when further medical or surgical treatment is required, the shoes must be adjusted to conform to any changes such treatments make in the shape or size of the feet.

Pediforme shoes are prepared through experienced craftsmen to make the necessary adjustments as prescribed by the orthopedic surgeon or physician in these cases.

With purchases restricted it is readily apparent that substantial shoes, capable of reconstruction or easy adjustment, should be prescribed. For all practical purposes, Pediforme footwear may well be considered in shoe therapy.

# 'Particularly valuable'

• Globin Insulin with Zinc is "particularly valuable... in regulating patients who have a rise of blood sugar after eating only." reports Herman O. Mosenthal, M. D. (J. A. M. A. 125, 483-488, June 17, 1944.)

Diabetics of this type who are well controlled throughout the twenty-four hours with a single injection of 'Wellcome' Globin Insulin with Zinc, depend for this control on Globin Insulin's rapid onset of action and sustained day-time effect. Its diminishing action at night tends to minimize nocturnal insulin reactions

'Wellcome' Globin Insulin with Zinc is a clear solution and, in its freedom from allergenic reactions, is comparable to regular insulin. It is accepted by the Council on Pharmacy and Chemistry, American Medical Association, and was developed in the Wellcome Research Laboratories, Tuckahoe, New York. U. S. Patent No. 2,161,198.

*Available in vials of 10 cc., 80 units in 1 cc.*

## IN LICHENOID AND *Papular Eruptions*

In the management of lichenoid and papular eruptions, Tarbonis provides many advantages over the older tar preparations, without in the least sacrificing the efficacy of crude tar. It is free from all tarry odor. It is non-greasy. . . it is non-staining, non-soiling, neither to the skin, nor to linen or clothing. It is virtually non-irritant, hence it may be applied as frequently as needed.

Therapeutically its action is dependable. It relieves the harassing pruritus, stops scratching, improves blood flow and lymph circulation, hence is anti-inflammatory and decongestant.

For the ambulant patient Tarbonis is especially gratifying. It does not interfere with work or social activities. Since its vehicle is a vanishing-type cream, it leaves no trace upon the skin, it is not detectable by odor, it obviates the annoyance and frequent embarrassment which greasy,

odorous tar preparations usually engender.

Tarbonis owes its efficacy to a liquor carbonis detergens extracted from selected crude tar by a method distinctly its own. Of this extract it combines 5% with lanolin and menthol in a special vanishing-type cream. It is of established value in eczema, seborrheic dermatitis, certain tinea infestations, lichen simplex chronicus, in industrial dermatoses (almost regardless of the offending irritant), in fact whenever tar is indicated. • Tarbonis is available on prescription through all pharmacies and for dispensing purposes through accredited supply houses. It is packaged in 2¼, 8, and 16 oz. jars and 6 lb. containers.

Physicians are invited to send for clinical test sample and complimentary copy of the new, comprehensive brochure on tar therapy THE TARBONIS COMPANY, 4300 Euclid Avenue, Cleveland 3, Ohio.

Babies And Toddlers In Your Care*

**Meats**—Among the delicious, scientifically prepared Heinz Strained Foods for infants are nutritious Beef Broth with Beef and Barley, Beef and Liver Soup, and choice Vegetables with Lamb. Two special Heinz Junior Foods—Chicken-Farina-Vegetable Porridge and Lamb and Liver Stew—furnish important protein values for older babies.

**Fruits**—A well-balanced fruit-and-cereal combination, Heinz Strained Apricots and Oatmeal is a dish small babies enjoy. Heinz Strained Prunes, Peaches, savory Pears and Pineapple, and Applesauce, are bland, enticing fruits—not too sweet, not too tart.

**Vegetables**—Heinz makes Strained Beets, Carrots, Green Beans, Spinach, Peas, Tomato Soup and Vegetable Soup for babies. These specially grown vegetables are scientifically cooked and vacuum-packed to retain a high degree of minerals and vitamins . . . For older babies, Heinz prepares Creamed Tomatoes and Rice, Creamed Green Vegetables, Chopped Green Beans, Chopped Spinach and Chopped Mixed Vegetables.

**Desserts**—Creamy Heinz Strained Custard and Apple Prune Pudding are light, energy-giving, easy for infants to digest. Pineapple Rice Pudding and Prune Pudding—both highly nutritive Junior Foods—are two desserts you'll want to recommend for toddlers!

## **ARGYROL THE PHYSIOLOGIC ANTISEPTIC**

There are important properties in addition to bacteriostasis which make ARGYROL the "Physiologic Antiseptic"—one which works in harmony with the normal defense functions of tissue, nerves, cilia, and circulatory system. Of first importance is the fact that ARGYROL is both antiseptic and decongestive. But there is an EXTRA FACTOR in mucous membrane antiseptics, in decongestion with ARGYROL. This is physiologic stimulation of tissue defense function. It is a combination of physico-chemical and bacteriostatic properties which go far beyond the usual concept of what an antiseptic should do. Write for further details, posological table and booklet of clinical application.

Speedy correction of postsurgical anemia is a valuable contribution to rapid recovery. Through unfavorable influence on gastric secretion, on appetite, and on the sense of well-being, anemia interferes with food intake at the very time when nutrition is of paramount importance.

The requirements in postsurgical anemia are best satisfied when, in addition to iron, the factors are supplied which are essential to . . . optimal iron utilization . . . the promotion of appetite and intestinal function . . . stimulation of a feeling of well-being.

Heptuna provides not only an adequate amount of highly available iron but, in addition, the fat-soluble vitamins A and D, and the B-complex vitamins (partly derived from a vitamin-rich liver extract and yeast).

## Editorial

### Plain Talk, IV

Speaking before the Fifth District Branch Meeting of the Medical Society of the State of New York, at Utica, September 19, 1944, President Herbert H. Bauckus said, in part, "Man in his better moments has sympathized most hopefully with the proposition that all men are created free and equal. In the practical application of this thought is found again and again the strength and the faith that has nurtured our liberty—that has made America great. So, too, do we of the profession of medicine adhere steadfastly to the belief that all who live shall benefit alike according to the skill, ability, and resource of the highest developments in medical science available today. . . ."

President Bauckus called upon the responsible agencies of government charged with the responsibility of providing for the needs of the economically unfortunate to secure for these the same quality of medical care available to others.

"That this group, doubly unfortunate when ill, do not secure it, is not our fault—rather it is the result of the effort of the Boards of Social Welfare to buy cheap medical care. We do not want the product adulterated, no matter who pays for it. Political welfare medicine, cheap and hastily

conducted school examinations, crowded and undersupplied clinics—we do not want them. Why do those outside of the medical profession insist that we shall have any such impersonal and poor medical care in this richly endowed America of ours? . . . ."

Why, indeed? Because public business is that way in the nature of things; public officials, hard-working, ill-paid for the most part, some appointed for political reasons rather than for their knowledge, always under critical fire for their expenditures of public monies, are not in a position to do as they please. Restrictions laid down by higher authority govern, often under penalty for noncompliance of loss to the communities or districts or states of monetary grants-in-aid or rebates of tax monies. This is the curse of subsidy. This is the compelling reason why physicians look with disfavor upon the tendency to expand schemes for government or government-controlled practice of medicine.

"Our interest in preventive medicine likewise calls for the highest standards. We educate against epidemic disease, careless living, dangerous working—we warn against gambling with health and disease.

"Why do we need to have so many or-

ganizations to cope these many weary years with the problems of insanitation and preventable disease? I think a study of this question will reveal three main causes: (1) lack of leadership in the profession of medicine in public health procedures and their successful application to a properly informed people; (2) inertia and lack of carry-through to the use of our best medical knowledge on the part of officials of government—executive, law-making, finance, judicial; (3) health departments and boards of social welfare hampered by undermanned personnel, lack of funds, and political considerations.

"Our part, then, is to assume to the full our rightful leadership in the entire fields of the medical arts and sciences. No others are trained to understand or do as well. We ourselves do better. What does it profit anyone to keep with us this great preventable scourge, tuberculosis?

"I have no patience with those who quote statistics of 100 deaths being relatively unimportant when compared to 1,000 deaths. There is no place for coldness, and every place for warmth and mercy, in modern medicine."

Warmth and mercy, compassion, tenderness, the human relationship of one individual to another, the practice of medicine, or nursing! Can anybody visualize a Federal Warmth and Mercy Administration? A State Department of Compassion and Tenderness? The strength of government should lie in its impersonality, in even-handed administration of justice under the law, in the honesty and impartiality of its executives, in the incorruptibility of judges, in the accessibility of the courts of law to all.

Because there is this difference in the very nature of constitutional government and the practice of medicine, the government has no place, and, if constitutional, a government of laws, no sympathy, by definition, with the practice of medicine. It should have, quite properly, regulatory powers over the practice of medicine, provided these powers are wisely exercised under statutes which recognize the freedom necessary to the proper exercise and development of that which is partly a science and partly an art. But, as Dr. Bauckus says, leadership must come from within the informed profession. With assistance, not

meddling, with lawful regulation, not control, by government. Failure by government to recognize these limitations, failure to exercise them, is to debase a profession, to demean government, and to substitute coldness for warmth, impersonality for a necessary humanism quite proper in the practice of medicine.

"To provide for the cost of medical care is a problem we have earnestly and considerately discussed with society in general and the individual patient in particular. We believe that our efforts to found voluntary prepayment medical care insurance plans in New York State are gradually bearing fruit. The establishment of a medical care insurance bureau with adequate personnel under the aegis of the Medical Society of the State of New York is a decided forward step, and evidence of our faith in the public appreciation of independent medicine.

"Any sane consideration of the cost must put hospital and medical care among the foremost needs. Food, clothing, shelter, medical care—they are essentials and not to be entrusted to the vagaries of chance. Our leadership must be constructive in the emphasis upon liberal public education in preventive medicine and the care of the mind and body in health and in disease. We cannot delegate our responsibility in this regard. . . ."

We have, however, much to learn. If we cannot delegate our responsibility, we must exert our authority within the profession to enlarge our plans for voluntary prepayment medical care insurance. Our own profession must be educated, and quickly, to acceptance of this responsibility and to the necessity for the widest possible coverage of the population. It is hardly practicable, even if it were desirable, to insure one-half the employees in an industrial plant. Which of us would insure one-third of his automobile or one-sixth of his house?

Public appreciation of independent medicine seems to be evidenced by its support of the practitioners and the institutions of that kind of medicine. But there is much danger of alienating public support and confidence by too great independence. There is a happy medium and we would do well to take public need as a criterion and proceed accordingly.

## For the Record

Just for the record, we reproduce from the sources noted the pertinent portions of the national party platforms that relate to medical care, however remotely

*Republican Platform (under "Security")—New York Times, June 28*

1 Extension of the existing old age insurance and unemployment insurance to all employees not already covered

2 The return of the public employment office system to the State at the earliest possible time financed as before Pearl Harbor

3 A careful study of Federal-State programs for maternal and child health, dependent children, and assistance to the blind with a view to strengthening these programs

4 The continuation of these and other programs relating to health and the stimulation of Federal aid of State plans to make medical and hospital service available to those in need without disturbing the doctor patient relationship or socializing medicine

5 The stimulation of State and local plans to provide decent low-cost housing properly financed by the Federal Housing Administration or otherwise

when such housing cannot be supplied or financed by private resources

*Democratic Platform (Section IV)—New York Times, July 21*

There is no direct reference to health security except for this in Section IV

"We assert that mankind believes in the Four Freedoms"

"We believe that the country which has the greatest measure of social justice is capable of the greatest achievements"

Our membership will have come to its own conclusions, we hope, ere this and will be prepared to support what it believes to be for the best interest of the Nation, regardless of party

In these times that try men's souls, times that sear and burn, men seek the truth, discard the chaff, and move more directly to the goal of their aspirations than at any other time

Men of medicine will do their part as they always have in their capacity first as citizens, and then as physicians

## Cheerful News, But—

In spite of a general increase in lawlessness reported from many sections of the country during the war period, the death rate from homicide has been steadily declining, according to a well-informed source.<sup>1</sup> In view of the emphasis which has been placed on the alleged increase in juvenile delinquency, and the widespread opinion that wartimes tend to increase delinquency not so juvenile, it is encouraging to read that

"this drop in mortality is not merely a wartime phenomenon, the homicide record of the United States has been improving without interruption for more than a decade. The death rate from this cause fell from 9.7 per 100,000 population in 1933, when nationwide data first became available, to 5.8 in 1942, a decline of about 40 per cent. More recent data have not yet been released for the country as a whole, but reports from various sources, including the experience among the many millions of Metropolitan industrial policyholders, indicate that the homicide situation has continued to improve since 1942. It is quite likely that the current rate is the lowest ever experienced in this country."

Yet before we take too hopeful an attitude, it is as well to remember that homi-

cides took more than 7,700 lives in the United States in 1942

Since 1933, it is said that the homicide rate has shown a downward trend in general, and in forty-one states (including the District of Columbia), the decline has amounted to 25 per cent or more between 1933-1934 and 1941-1942, in twelve States the decrease was 50 per cent or more.

We fail to note the Empire State listed among those arranged according to magnitude of relative decline. But on the other hand, it is not listed either among the States in which the homicide rate is well above the national average, and which, commendably, have shown marked reductions in mortality. Physicians are interested in the reduction of the mortality rate from whatever cause. They will note with interest that

"The general reduction in murder and manslaughter in this country may be attributed to a number of factors. There is reason to believe that the tightening of restrictions on the sale and possession of firearms has had a salutary effect. Thus, in 1933 firearms accounted for 65 per cent of the homicides in the United States, but by 1942 the proportion had decreased to 54 per cent. Law enforcement agencies—Federal, State, and local—have, in gen-

<sup>1</sup> Statistical Bull. Met. Life Ins. Co., September 1944

eral, been functioning more efficiently in combating the criminal element in our population. The Federal Bureau of Investigation deserves special mention for its effective attack on racketeers and gangsters. But this is by no means the whole story, or even the major part of it. Professional criminals, studies show, are responsible for a fairly small proportion of the homicides. A majority of such killings arise over petty disputes and quarrels or from jealousy or thwarted love."

Among the other causes to which reduction may be attributed, says the same source,

"It is probable that improvements in social conditions have played their part. The clearance of slum areas, which frequently breed lawlessness, and increased facilities for wholesome recreation, must have had some effect. The fact that education has become more widespread is another factor to be taken into account, because investigators have found that a large proportion of those who commit homicide have had very limited schooling. Community agencies have helped to prevent homicide by

giving increased attention to the care of problem children and adolescents. . . ."

On the whole it seems probable that continued restriction in the sale and use of firearms and ammunition would provide a simple and effective means of continuing and perhaps improving the record. Improvement in social conditions and education are relatively slow processes; slow but sure. Restriction in the sale and use of firearms and ammunition is a measure which all physicians could approve and which we could and do recommend to the thoughtful consideration of the Legislature. We see no reason why the Empire State should not set an example in this as it has in so many other fields. Surely we have had enough of unavoidable homicide forced on us. Why make a bad matter worse?

### Penicillin for Sulfonamide-Resistant Gonorrhea\*

Penicillin has been made available by the State Health Department to all physicians for the treatment of sulfonamide-resistant gonorrhea. It may be secured by application to the nearest district State Health Officer, or, in some of the larger cities, to the local health officer. Unfortunately, the high cost of penicillin prohibits its distribution in the informal manner in which the sulfonamides have been made available. The

district State Health Officer has been requested to ascertain that a case report for gonorrhea has been or will be submitted for each ampule of the drug, that the infection has been resistant to the sulfonamides, and that the contacts of each case have been identified, in order to forestall reinfection, which is common after penicillin therapy. Patients will be questioned for the names of their contacts, and the persons thus found will be brought to examination by the State and local health departments.

As an additional measure, posters are to be placed in the washrooms of taverns and pool halls, in an effort to influence persons with untreated gonorrhea to report to physicians for diagnosis. (See Chart 1.)

The format and content of this poster are designed to attract particularly those people who commonly seek the quack or attempt self-treatment of gonorrhea. For this purpose the poster must be brief and dramatic and hence will be misunderstood by some. It is thought that the commonest misinterpretation of the text of the poster at the left will be that treatment as well as the drug is free. Qualification to preclude this misapprehension is likely to curtail the utility of the poster. The assistance of the practicing physician in this effort to bring to medical care that fraction of the population least frequently seen in the physician's office, but most important in venereal disease transmission, is solicited.

# AN EVALUATION OF CONTINUOUS CAUDAL ANALGESIA

CLIFFORD B. LULL, M.D., and ROBERT A. HINGSON, M.D., Philadelphia

SINCE 1942 we have published, individually and in collaboration with our associates several articles on continuous caudal analgesia which have dealt mostly with our observations and experience in the use of this method in vaginal delivery, cesarean section and gynecologic surgery. We have particularly stressed the "don'ts," the "stop, look, and listen" signs which must be observed if successful caudal analgesia is to be obtained with safety for both mother and child. We wish to reiterate these cautions, and although we feel that this technique has passed beyond the experimental stage in the hands of trained individuals, inexperienced physicians must be cautioned continually.

As we have gradually extended the scope of its use and gained further knowledge of this technique, we have endeavored to give the medical profession our unbiased opinion of this procedure in the relief of pain.

After employing this method in several thousand instances we are convinced that teamwork between the anesthetist and the obstetrician is essential for the proper accomplishment of this technique. The many problems that have developed in this study could not have been solved in any other way than through the constant cooperation of these two hospital departments. Because of the shortage of personnel, trained anesthetists in particular, many clinics have hesitated to initiate the technique of continuous caudal analgesia and we believe rightly so because we have consistently contended that this is a procedure to be used only by trained individuals in well-equipped and well-staffed institutions.

When Hingson and Edwards first startled the medical profession with their preliminary report, the lay publicity given to their work created a great furor. Since that time we have been endeavoring to study and adjust the many problems which have arisen so that this work might be placed on a foundation which will not only be permanent as far as medicine is concerned, but will safeguard the laity from its misuse.

Continuous caudal analgesia, which was not originated on the pages of any popular lay magazine, was scientifically designed to relieve the pains of labor and delivery. A single expert movement of a physician's hand provides the bulwark which divides on one side comfortable labor and delivery from the agony of travail on

the other. The primary duty of the physician is to relieve the processes of pain. The second duty, not unlike the first, is to allay the processes of fear. Pain can be brought to a frightful nearness through the telescope of fear. Fear can be greatly accentuated and magnified through the microscope of pain. These two processes are pathologic psychic gemini, which when present in an uncontrolled form may periscope into the sensorium an irreversible psychic trauma. The control of pain is achieved by two methods: (1) the anatomic approach—that is, by blocking pain impulses at their sources, as in local, spinal, regional anesthesia, and caudal analgesia, (2) the encephalic approach—that is, by obliterating pain at its site of interpretation in the central nervous system through various forms of general, intravenous, and rectal anesthesia. The patient in whom fear is completely controlled is the ideal one for the use of the anatomic approach. The one in whom fear is uncontrolled can be relieved usually more satisfactorily by one of the forms of general anesthesia or amnesia. We have demonstrated in thousands of instances that an adequate dosage of a local analgesic properly injected into the sacral canal, through a single needle, will produce sufficient nerve block for cholecystectomy, cesarean section, appendectomy, or normal delivery. It is an untenable thought to us that the jeopardizing seven needle technique of sacral block still has a place in medicine for such minor procedures as hemorrhoidectomy, when analgesia of the lower two-thirds of the body can be produced by the use of just one of those needles.

The physiology of labor and delivery observed by the midwife and interpreted in our existing textbooks on obstetrics is completely altered since the inception of successful continuous caudal analgesia. In the presence of forceful uterine contractions the progress of labor through the first stage is dramatically shortened. The softened cervix, oftentimes within the hour, dilates from 3 to 5 cm. to 10 cm. with an associated rapid advancement of the presenting part to the perineum. If the obstetrician in these cases performs his function properly, a baby will be born which cries the moment its nose crosses the perineal floor, the third stage of labor will be shortened and simplified to the point that in many instances third-stage hemorrhage will be unbelievably small.

The convalescence of the patient who has been properly managed under caudal analgesia pre-

sents a reduced minimum of morbidity. The rapid involution of the uterus, the return of the cervix to the prepregnant state, the good muscular tone of the perineum at the six-week check-up period, have convinced us that postcaudal-analgesia parturients more nearly approach the nulliparous state than those managed under other technics. This finding has been substantiated by the observations of Dr. Francis R. Irving of Syracuse University.

In the phylogenetic development of the human species, there is an axiom in anatomy which scientists and physicians have used to advantage; namely, the *Ascensus Cordae Spinalis*. At the third month of fetal life the spinal cord, surrounded by the spinal fluid and meninges, extends the full length of the anlage of the vertebral column. The conus medularis, or the bulb-like termination of the neural axis, in the three-month fetus as in the quadruped mammals extends inferiorly to the sacral hiatus. During each succeeding month of intrauterine life until adulthood has been reached there is a relative ascensus of the spinal cord as the somatic vertebral column develops more rapidly caudad.

By the time the infant has reached the second month of life the spinal cord has receded and terminates at the fourth lumbar segment. At the age of five years the conus medularis is found opposite the third lumbar segment. At the age of 11 years the conus medularis lies opposite the second lumbar segment. In adult life the spinal conus medularis lies opposite the first lumbar segment, and in unusually tall individuals the ascensus has proceeded to more thoracic vertebral segments. Conversely, dwarfed individuals have spinal cords and dural sacs extending more inferiorly.

J. Leonard Corning, of New York, took advantage of this phenomenon to produce the first spinal anesthetic in 1885. Quincke utilized this information to produce the first diagnostic lumbar puncture in 1891. August Bier, of Kiel, Germany in 1898 combined the technic of the latter with the discovery of the former to produce the first spinal anesthesia in surgery, only after he, with temerity, had his own subarachnoid space injected with 20 mg. of 1 per cent cocaine solution to observe its effects.

During the ascensus the spinal cord sluggishly retracts the paired segmental nerves in the lumbar and sacral regions into the cauda equina. The dura mater is also relatively retracted as the sacral segments continue to grow beyond its inferior extremity at usually the first or second sacral spine. The osseous neural canal of the remainder of the sacrum comes to lie outside and beyond the dural sac, and hence becomes continuous with the peridural space. Sicard

and Cathelin, in 1901, took advantage of this fact to produce the first nerve-block experiments through the approach of the sacral hiatus.

The charm of the tunnel within the sacral canal enchanted the Greek anatomists to believe that the sacrum or the "sacred bone" became at night the sepulcher of the soul during sleep. This analogy closely approximates the truth, when we consider that through the sacrum traverse the nerve fibers controlling locomotion, micturition, defecation, parturition, and reproduction. Through the afferent pathways run the impulses of pelvic and sciatic sensation and pain.

Thus a study of the osteology of the sacrum, the neurology of the segmental spinal nerves, the physiology of the pelvic viscera, and the pharmacology and anesthesiology related to the control of pain in these organs seems appropriate.

During the last three years we have, in co-operation with J. Parsons Schaeffer, dissected the spinal cords, peridural spaces, and sacrum of 241 cadavers. We have observed that the anomalies of the sacrum are more prevalent than those found in any other bone in the body. Trotter and Letterman, in a study of more than four thousand sacra in the Washington University School of Anatomy, and in the Western Reserve University anatomic collection group, have found the more common anomalies in the following ratios:

Twenty-two per cent of all sacra studied had accessory openings in the roof. More than 11 per cent had a bony defect at the superior pole produced by a failure to close by the first and second, or first, second, and third dorsal arches. Eight per cent produced bony defects in the inferior pole with a failure to close of the lower three, or lower two dorsal arches. Five tenths or 1 per cent of female sacra, and 2 per cent of male sacra exhibited no roof at all.

Recently, another anatomic study has revealed the absence of sacral corpora, or a hemisacrum with an associated sacrocele in six patients. All of the latter group were first diagnosed as ovarian cysts. Observation, however, revealed the real pathology. All of the patients died of meningitis. Various investigators have discovered that anomalies of the human sacrum are from four to six times more frequent in the male than in the female. For this favoritism toward our work we can find no fault with nature.

In 5.5 per cent of 2,600 sacra, Trotter and Letterman have determined that the insertion of the recommended sizes of caudal needles is practically impossible because of osseous obliteration of the sacral canal; diminished antero-posterior diameter also precludes the use of caudal analgesia.

The identification of the sacral hiatus through the recognition of topographic landmarks is of cardinal importance in the successful application of this technique. A failure on the part of the physician to observe this warning will develop into an insurmountable difficulty for the doctor, and an irreparable hazard to the patient. For example, in our postgraduate medical course twenty-eight of three hundred sixty physicians inserted caudal needles in such a manner as to bypass the coccyx and enter the rectum. One physician in a large university hospital, performing his first caudal block, inserted the needle through the rectum, through the vaginal wall, through the cervix, through the baby's parietal bone, and into the cortex of the brain, where he lethally deposited the dose of the local anesthetic. Obviously, special training is necessary to perform this difficult technique. The inferior tip of the coccyx, the sacrococcygeal articulation, the sacral cornua with their projecting tubercles and the palpable depression of the sacral hiatus should be identified by the anesthetist before he attempts the introduction of the needle. Ninety per cent of the sacral hiatus lie at the intersection of the superior pole of the intergluteal crease with the isosceles sacrogluteal grooves. This hiatus varies in size and shape in different individuals. More than three fourths of the hiatus are slightly smaller than the forefinger nail. We make a practice in our prenatal clinic to determine ahead of time the condition of the sacral hiatus by palpation. Thus the patients with easily palpated sacral hiatus are listed on the examination chart. Those in whom the hiatus cannot be felt are declared unsuited for caudal analgesia in routine cases. However, when special medical indications, such as tuberculosis or heart disease are present, these patients are x-rayed by the Bishop modification of the Moloy technique for a special sacral study. These x-rays are produced by a fifteen degree angulation of the roentgen tube to direct the ray through the infrapubic approach.

This is one of the most important supplementary techniques that have been added to caudal analgesia since its introduction.

In numerous medical publications we have already substantiated the pioneer work of Cleland, who was the first to accurately locate the afferent uterine neurology.

In more than 3,000 personally observed and managed obstetric patients we have not found a single case in which a complete block of the eleventh and twelfth thoracic nerves was not accompanied by a total relief of the abdominal cramps of labor. Likewise, we have not found a single case in which well-established contractions of the uterus did not continue if the level of analgesia

was not permitted to rise above the tenth thoracic segment. Thus we have confirmed the natural anatomic dissociation between the motor and sensory components of the uterine nerves. This fact makes possible the clinical application of caudal analgesia in such a manner that the pains of labor are relieved and the cramps of labor continue without interruption.

A third component of uterine neurology should also be considered, namely, the nerve supply to the cervix. The nerve fibers which run to this fibromuscular structure have been determined to be both sympathetic and parasympathetic with ramal communications to the second, third, and fourth sacral somatic nerves. The afferent divisions of these nerves transmit the sensation interpreted by the parturients as the intense, agonizing crescendo of pain across the lower back.

The afferent components produce a more or less constant contraction of the smooth muscle bundle guarding the cervical os. Thus an anesthetic block of these nerves produces a welcome relief of pain and a relaxation of musculature which, in the presence of forceful uterine contractions from above, develops into a rapid dilatation and expulsion of the baby through the birth canal.

The pudendal nerve block, advocated by De Lee and championed by Greenhill, is more surely accomplished at the same time by the single caudal needle than was ever accomplished in the hands of the masters who used the human perineum as a bilateral pin cushion, which required psychosomatic medicine or the equivalent of nitrous oxide as a supplement.

The sympathetic motor fibers which proceed from the upper thoracic regions down the aortic plexus, through the celiac ganglion with reinforcements from the renal and genital ganglia, continue along the hypogastric arteries into the pelvis and through the great cervical ganglion of Frankenhauser to the smooth muscles of the uterus which they cause to contract. The fibers transmitting stimuli interpreted as abdominal labor or menstrual cramps proceed through sympathetics as special visceral afferents. These fibers do not synapse in the sympathetic ganglia, but they proceed directly through the structures of the eleventh and twelfth thoracic rami communicantes to the dorsal spinal root ganglia, and from thence into the dorsolateral fasciculus in the zone of Lissauer and up the posterior columns through the midbrain to the thalamus. Historically, this pain pathway should be known as the nerves of Cleland. Other fibers transmit impulses which control cervical dilatation, and influence uterine inhibition. As indicated, they run through the second through the fifth sacral segments.

The nerves of particular concern in this technic are those of the pudendal and perineal plexi.

Some uteri during labor do not exhibit forceful contraction. In some, the labor seems to be delayed because of an emotional endocrine dysfunction. We therefore present the following information which has not been reported previously:

Continuous caudal analgesia, improperly applied, can retard or actually stop the progress of labor! We have observed these phenomena clinically. We have substantiated them with the tocograph. There are three types of response of the uterus to caudal analgesia.

In from 40 to 60 per cent of the patients there is no significant change in the force, frequency, or duration of the pattern of uterine motility under caudal analgesia. In these patients labor progresses more rapidly than we ordinarily would expect because of the relaxation of the cervix and perineum. Thus in these instances the first stage of labor is definitely shortened, as the presenting part promptly descends to the perineum. In the majority of primiparas there is not sufficient somatic muscular power to deliver these babies spontaneously and simple outlet forceps will expedite the labor safely for both mother and baby. The third stage of labor can often be terminated, as indicated by Vaux and Mitchell, within one and one-half to two minutes, by simple expression of the placenta with simultaneous manual retraction of the corpus uteri over the promontorium of the sacrum and out of the pelvis. In these instances more than one half of the patients will lose less than 50 cc. of retroplacental blood. As a rule, these are the patients who definitely go into labor with uterine contractions that are three minutes apart and less, and with three to five cm. of cervical dilatation before continuous caudal analgesia is begun. The great majority of these patients have their babies within two to five hours after the institution of caudal analgesia. In this group the babies are more vigorous, exhibit less birth shock, and are born with their eyes wide open. They breathe and cry vigorously from five to thirty seconds after their heads are born.

The second type of uterine response occurs in from 20 to 35 per cent of patients. In these there is a constant diminution in uterine tone with increased amplitude of contractions. In some of them there are prolonged intervals between contractions. These labors, like the first group, progress rapidly and are terminated successfully. In both groups described above, the level of analgesia has not been permitted to proceed above the ninth thoracic segment.

In the third group of patients the uterine tone may be increased and there is a diminution of the

amplitude of the contractions. These responses are frequently associated with a high level of ascent of the analgesia to the point of the fifth to first thoracic segments. In these patients the labor pains are ineffectual. The progress of labor is retarded. In these also we have determined by auscultation of the fetal heart a bradycardia which is our most reliable indicator of fetal anoxia.

In four patients who were brought into the hospital because of violent trauma from such accidents as automobile wrecks or falls from a moving trolley, we first carried the level of analgesia to a high thoracic segment, unintentionally, to find that the almost tetanic contractions of the uterus ceased. In two of these patients in whom we had, at the moment, non-viable babies because of prematurity, we completely arrested labor to the point of delay of several weeks. In both of these patients we subsequently delivered babies which lived. Recently, therefore, in three other patients with premature babies we have attempted to stop labor. Once we were successful. Twice labor proceeded with unusual rapidity even though the level of analgesia extended to the clavicles.

We would like to emphasize to the profession that the correlation of further studies with the Murphy technic of the Lorand tocograph upon the uterine motility patterns of patients undergoing caudal analgesia will reveal concrete, fundamental physiology about which we now understand so little. The work of Frankel, who initiated this study, has been the most valuable single contribution of the year in this subject.

We have surveyed the current literature and have found that the three drugs most commonly used in this technic are metycaine, procaine, and pontocaine. All of them, in the hands of their advocates, have produced satisfactory results. We insist that physiologic saline or the three chlorides of Ringer's solution be the vehicles of dispersion of this drug in preference to distilled water. One and one-half per cent metycaine and 1.5 per cent procaine produce clinical results of such similarity that it is hard for the inexperienced to choose between them. We have substantiating evidence that metycaine, though clinically no more toxic than procaine, is definitely more potent. We prefer its use for the following reasons:

1. The intensity of the nerve block of the pain fibers is uniform and with Ringer's solution is definitely prolonged an extra ten to twenty-five minutes.
2. There have been a minimum of complications due to pharmacologic reactions to this drug.

3. The recovery of the nerve fibers with the return of normal body metabolism and function is more prompt and is followed by fewer sequelae.

4. Metycaine, a substitution product for cocaine, is synthetically derived from coal tar. It is, therefore, more stable in the presence of heat, pressure, and prolonged exposure to light than any of the known local analgesics. For that reason it can be reautoclaved and used with uniform efficiency many months after its procurement. We have not yet determined the upper limits of the body's metabolism and excretion of this drug. We have administered 11,000 mg. to each of nine patients over many hours without undue effects. We have injected 26 pounds of metycaine into the peridural space, when it exerts its pharmacologic control of pain for a minimum of forty and a maximum of one hundred and sixty minutes with a single dose. It can be repeated as an injection for as long as necessary. Our longest analgesia in obstetrics extended over a thirty-three hour period, during which time the travail of the mother's uterus was transposed onto the shoulder of the physician.

Metycaine is absorbed by the blood stream, and is metabolized partially by the reticulo-endothelial system of the maternal structures. A part of it is excreted through the kidney in demonstrable quantities in the maternal urine. Minute quantities of it pass through the placenta into the fetal circulation to produce what we have interpreted as a stimulation to the fetal nervous system. On two occasions after prolonged analgesia we have found evidences of metycaine in the first postdelivery fetal urine. Thus far in twenty chemical analyses of the amniotic fluid we have not found any metycaine therein.

Pontocaine in 0.10 to 0.25 per cent solution produces some analgesia which in a few patients is ideal, since it persists for two to five hours from a single dose. However, the intensity of the block of the pain fibers is never so great as with procaine and metycaine. Clinically, we have observed increased nausea from the use of this drug. The fact that it requires from ten to forty minutes following injection to produce total pain relief precludes its use from terminal delivery.

The complications associated with this technic were recently reported by us to the profession in our analysis of the first 10,000 so managed. During the past three years 36,000 babies have been born to mothers laboring without pain under continuous caudal analgesia. It has been alleged that this technic would never become a part of our obstetric armamentarium. It has also been declared that the fad of continuous caudal analgesia would soon be forgotten. Our

reports indicating that already more than 200 babies have been born with this technic in Persia, 50 in the Dominican Republic, 7,000 in Philadelphia, 3,000 in Brooklyn, 2,000 in San Francisco, 2,000 in San Antonio, 1,000 on Staten Island, 1,000 in Chicago, 1,000 in western Maryland, 850 in Syracuse, 400 in London, and 200 in Manhattan, seem to present ample evidence that continuous caudal analgesia is here to stay. The original 33 patients managed by this method were done at the Marine Hospital, Staten Island. Because of enlarged facilities in Philadelphia, most of the work, although continued at Staten Island by Edwards, has been carried out at the Philadelphia Lying-In Woman's Department of the Pennsylvania Hospital, and the Jefferson Medical College. It now becomes necessary for us to consider ways and means of educating the physicians to perform this technic while at the same time safeguarding the patient from the untrained physician who attempts to apply the method without fundamental knowledge of the basic medical science.

To meet this demand we have established, through the combined efforts of the United States Public Health Service under Surgeon General Parran, and the staff of the Philadelphia Lying-In unit of the Pennsylvania Hospital, a postgraduate medical course dedicated to the task of training the obstetrician and the anesthetist in conjunction with a specialized nursing supplement.

Already, with our limited facilities, we have trained 450 physicians from thirty-nine of the United States, six from the Provinces of Canada, fifteen from the Latin American countries, and five from the Continent of Europe. We have been aided in our task by the faculty and teaching facilities of the Jefferson Medical College. Our researches have not been limited to obstetrics, but include the use of this method in surgical cases, peripheral vasospastic disease, thrombophlebitis, peripheral arterial embolism, sciatica, pruritis ani, and traumatism of the lower extremities. The use of this method offers a promise of therapy to patients suffering from the ischemic stage of "immersion foot" described in the torpedo victims of the war at sea.

Continuous caudal analgesia may also be used as a diagnostic and prognostic procedure to determine indications for amputation of one leg in occlusive vascular disease. If clinical improvements can be produced for a few hours or a few days under continuous caudal analgesia, we have a valuable indication for the performance of lumbar sympathectomy.

Early in our experience we observed the dramatic reductions in both systolic and diastolic blood pressures in patients suffering from

TABLE 1

Total number vaginal deliveries.....	1,948
Total number under caudal.....	963 (49.4 per cent)

hypertension. Some of these blood pressure falls have been greater than 150 mm. of mercury. With these falls in blood pressure there has been a clinical improvement in the patients during the course of treatment with an alleviation of the accompanying headache and blurred vision. To our surprise, a few of these patients have maintained a markedly reduced blood pressure for as long as two days to three weeks following six hours of therapy with continuous caudal analgesia. We are therefore able to use this method as a pilot indicator of the effect to be attained by sympathectomy.

Our work with this technic in more than forty patients with eclampsia and associated convulsions has been likewise encouraging. As soon as the parturient with this disease has had her blood pressure reduced from 50 to 100 mm. of mercury, her convulsions stop and she usually requests, and receives, water and liquid nourishment. On the basis of physiology we have noticed the following clinical phenomena:

1. A maximum vasodilatation of the lower extremities enormously increasing the capacity of the vascular bed far superseding the effect of *Veratrum viride*.

2. A lowered blood pressure which can be maintained constantly for hours.

3. A block of the vasoconstricting elements to the kidney, thereby increasing the flow of urine in these potentially anuric patients.

4. A temporary denervation of the suprarenal gland with a corresponding diminution in the manufacture of the endocrine vasospastic substance.

Our experience with the management of these patients without loss of mother life indicates to the profession that experts in metabolism, pharmacology, and obstetrics should unite with us in a study of this condition.

At no time, contradicting the many lay articles which have been written concerning continuous caudal analgesia, have we felt or even been inclined to believe that this method is a panacea for the pains of childbirth and we would like to point out at this time that we have at our disposal at least four other safe and effective means of inducing analgesia and amnesia. According to a recent article by Kotz, of Washington, and we quote from his article, "Each has certain peculiar advantages and disadvantages, but in capable hands all of them are of value. As in anesthesia, so in obstetrical analgesia, the agent used should

be the one best adapted to the particular case. Best results cannot be obtained by rigid routines. The obstetrician and the obstetrical anesthetist should be conversant with all methods, and constant attendance upon the laboring woman is necessary if proper supervision of the analgesia is to be carried out." Kotz is also of the opinion that a combination of the obstetrician and the anesthetist is ideal and is firmly of the opinion that every woman may be given complete analgesia and amnesia with safety for herself and her offspring, if sufficient attention to detail and sufficient personal supervision are available.

We are presenting our analysis of 963 patients delivered at the Philadelphia Lying-In Hospital from June 1, 1943, to May 1, 1944. The reason we have selected this series is that it includes all patients given caudal analgesia since the inception of our postgraduate school and more particularly because the analgesia has been administered by more than 300 different individuals. This includes the men taking our postgraduate course as well as our trained permanent staff. We have not included in the following report any patient delivered by cesarean section. Up to May 1 we performed 154 cesarean sections under continuous caudal analgesia without any maternal death and only one fetal death, which occurred at five and a half months' gestation, in a patient with severe toxemia. During the past three years we have used practically no inhalation anesthesia for our cesarean sections, and at the present time we are trying to evaluate the difference, if any, between the use of fractional spinal and continuous caudal.

At the present moment we are of the opinion that either one of these methods is eminently satisfactory and do not believe that there is a great deal of difference in the results obtained. A detailed report of the use of continuous caudal analgesia in cesarean section is being made in a separate communication.

Table 1 shows the number of vaginal deliveries at the Philadelphia Lying-In Hospital from June 1, 1943, to May 1, 1944. Cesarean sections and abortions are not included in this group. Of the 1,948 patients delivered vaginally, 963, or 49.4 per cent, were either delivered under continuous caudal analgesia or attempts were made to carry out the technic. We have included in this number all those patients who were considered suitable for this technic. In a previous communication we reported 52.9 per cent of patients who were considered suitable. The rapidly progressing multipara, the obese, the abnormalities of the sacrum, and other contraindications will rule out about 50 per cent of the routine patients admitted to the hospital. We have found, however, that

TABLE 2

Age Group	Patients	Percentage
10-20	95	9.9
21-30	608	63.1
31-40	253	26.3
41+	7	0.7
	963	100.0

the incidence of suitable cases occurring in private patients is about 60 per cent.

Table 2 shows the age group in these 963 patients. We thought we were going to be able to obtain some information from breaking this series into age grouping but upon closer analysis there is not much difference between the length of labor or the blood loss in any of these groups listed.

TABLE 3

Parity	Patients	Per Cent
0	458	47.6
1	310	32.2
2	97	10.0
3	70	3.1
4	7	0.7
Other	61	6.4
	963	100.0

Table 3 shows the parity. As is seen, the largest number were in the nulliparous class. So many of our clinic multiparae arrived in the delivery room far advanced with their labor that it automatically reduced the number a great deal in whom we were able to follow out this procedure.

TABLE 4

Presentation	Patients	Percentage
Anterior	820	85.4
Transverse	67	6.8
Posterior	34	3.5
Breech	42	4.3
	963	100.0

Table 4 shows the position of the presenting part. One of the frequent criticisms of continuous caudal analgesia is that it is the causative factor in posterior rotations of the occiput. Before we analyzed our last statistics we were of the same opinion, but find on careful scrutiny of our records that the incidence of posterior position was approximately the same as in those who had other forms of analgesia. Neither the transverse arrest nor the posterior position has given us any particular difficulty, as under caudal block it is much easier to rotate these heads into an anterior position, either manually or with the Luskart forceps. We have found that in the transverse position, by inserting one blade of the forceps and having the patient bear down with

TABLE 5

Method of Delivery	Patients	Percentage
Low forceps	577	59.9
Midforceps	71	7.4
Spontaneous	153	15.8
Breech extraction	42	4.4
Unrecorded (failure)	120	12.5

the uterine contraction, often suffices, with one or two contractions, to rotate the head to an anterior position.

Table 5 shows the method of delivery. The incidence of low forceps, 59.9 per cent, is approximately what we have averaged over a period of twelve years under all forms of analgesia. It has been our common practice to deliver practically all of our patients by outlet forceps. Therefore, the criticism that it increases the number of forceps deliveries, as far as our own clinic is concerned, does not hold true. We listed the forty-two breech patients as being breech extractions. However, we have found that under continuous caudal analgesia the extraction becomes quite simplified and in practically all cases is almost spontaneous. We have routinely, for years, used the aftercoming-head forceps on our breech extractions. Very frequently the delivery of the head in this group was so rapid by the expulsive forces of the uterus and having the patient bear down with the contraction, that we did not have time to put on the aftercoming head forceps. The 120 patients listed as "unrecorded" were those thought suitable for this technic, but who failed to obtain proper analgesia, as will be discussed later.

TABLE 6

Blood Pressure
Fall of 20 mm. systolic or more
284 patients (29.4 per cent)

Table 6 shows the number of patients who had a fall of blood pressure of 20 mm. systolic or more. The pharmacologic effect of caudal, spinal, and peridural analgesia without the addition of prophylactic vasopressor substances has been the production of hypotension. The dynamics of this hypotension are entirely mechanical. There is an extreme dilatation of the vascular bed of the lower extremities. Such a dilatation, because of the block of the vasomotor sympathetic nerve fibers, conceivably produces a diminution of the arterial pressure. The reason that the percentage in this group is as high as it is, is that about 50 per cent of them were handled without the use of ephedrine as a prophylactic measure. This was because we were interested to see how quickly the blood pressure would return to normal by merely raising the feet and

TABLE 7

Average length of labor	10 hrs. 23 min.
Average length of analgesia	3 hrs. 23 min.
Average blood loss	93 cc.

legs to right angles with the body axis, which produces an autotransfusion. The legs are held in this position for thirty seconds to one minute. Ninety per cent of these patients can be restored to their normal pressure by merely carrying out this procedure. The other 10 per cent have to be treated by the use of ephedrine in 25 to 50 mg. doses. Recently, in spite of the fact that the large percentage of these patients can be restored to normal by raising the feet, we have been employing the ephedrine more or less routinely, so that in our next series of patients reported, we feel sure that the drop in blood pressure will not be so pronounced. It should be pointed out that during extremely hot weather, when the parturients have lost considerable body fluid through diaphoresis and sometimes nausea and vomiting, there is no substitute for intravenous saline and glucose and, in the debilitated, blood plasma. It should be further emphasized that patients under caudal analgesia do not sweat below the level of the block. For that reason, during extremely torrid summer weather they should have their skin frequently moistened with wet towels or should be permitted to labor in air-conditioned rooms.

Table 7 shows the average length of labor to be ten hours and twenty-three minutes. We are thoroughly convinced that patients delivered under continuous caudal analgesia have a shorter labor than if managed in some other manner. The average length of analgesia seems to be quite short—three hours and twenty-three minutes. This, we find on careful analysis, is due to the fact that particularly in multiparas who are in well-established labor when the mety-caine is injected, the cervix will dilate very rapidly. We have observed on many occasions a cervix going from 3 to 4 cm. dilatation, provided it is completely effaced, to practically complete dilatation in just three or four uterine contractions. We are of the belief that if the ordinary discomfort of the effacement period of the first stage of labor is not too great and can be relieved by a small dose of seconal, usually 3 grains, and the caudal analgesia is started when dilatation averages about 3 or 4 cm., the cervix will dilate under its influence with great rapidity. In other words, just as in the management of any parturient, the analgesic selected should not be given too early. From our own experience we believe that the best results are obtained when the caudal analgesia is used for not more than

eight hours. The average blood loss in this series, as shown in this table, is 93 cc. We have had two patients in this series who had a blood loss of 500 cc. This occurred about twenty minutes after the termination of the third stage of labor. It has been our routine not to give any oxytocic drugs until after the placenta is delivered, as the uterus remains quite firm following the delivery of the child. The minimal blood loss has been one of the outstanding benefits derived from the use of this technic. In the most striking patient we have ever seen, a mother was delivered of large vigorous twins with a measured blood loss of 20 cc.

Table 8 shows that we have included in this series 120 patients who were thought suitable for this form of analgesia, but in whom it was unsatisfactory. As previously stated, we selected this group of patients to report because of the fact that over 300 doctors who were being trained in this technic handled the majority of these patients. We have routinely insisted that no more than three attempts to enter the sacral hiatus should be made and, as very frequently happened, the untrained individual bypassed the opening and the method was discontinued. There also was quite a large group in which abnormalities of the sacrum made it impossible to carry out the technic satisfactorily. An analysis of those patients given caudal analgesia by members of the staff who were trained in the technic decreases the incidence of failure to about 5 per cent, and in the past few months patients who were handled by these trained individuals show the incidence of failure to be further reduced. X-ray according to the Bishop technic has further reduced the incidence of failure by discovering unsuitable sacra before the onset of labor, thus ruling out these patients who were previously thought suitable.

Table 9 shows we have listed three maternal deaths occurring in these 963 patients. None of the deaths were attributable to the use of continuous caudal analgesia, but in view of the fact

TABLE 9

Mortality	
Maternal	
Fetal	None attributable to caudal analgesia

that these patients were handled by this method, it is only fair to list them under maternal mortality. All of these deaths occurred many hours or even days following the delivery. There were no fetal deaths attributable to the use of this technic, and, as has been pointed out in previous communications, the condition of these babies is particularly good at the time of birth. So much is this true that in delivering vaginally it is a good policy to rapidly sweep the chin over the perineum, as the only babies we have had any difficulty with were those that were seen to breathe when the head was partially delivered, and who insufflated a great deal of vaginal secretion. There were only a few of these, and they were immediately restored to normal by aspiration of the upper respiratory passages.

### Summary

In this communication we again call your attention to the care which is necessary in carrying out the technic of continuous caudal analgesia, together with a statistical report on 963 patients delivered at the Philadelphia Lyng-In Hospital and administered by 305 doctors who were being trained in this technic. This accounts for the higher number of failures than we find occurs when caudal analgesia is given by the trained anesthetist. These statistics, we believe, substantiate our belief that continuous caudal analgesia will become a permanent factor in the practice of obstetrics, particularly in the handling of premature babies, cardiac disease, respiratory infections, and the toxemias of pregnancy. Included in this paper is a summary of the recent supplementary work done in anatomy in several medical schools, with particular emphasis on the sacral hiatus, the sacrum, and the peridural space. The anomalies relating thereto have been emphasized. The present knowledge of the uterine by the Bishop-Moloy technic have been introduced. Tocographic determinations of uterine response under continuous caudal analgesia have been analyzed against the pharmacologic background associated with this technic. The incidence of complications and the contraindications indicate that this is still a technic to be performed by a specialist in the hospital.

### Conclusions

Almost every drug that has been found to possess pain-relieving properties in any branch of

the medical sciences has been used at one time or another in obstetrics. Many of the investigators with these drugs and technics have contributed just as much to the safety of the mother and baby in discouraging the use of certain technics as have the proponents of many of these measures with their efforts to relieve the suffering and distress of parturition. The fact that any patient undergoing obstetric management with amnesia, analgesia, or anesthesia should be surrounded by all the safeguards of a modern hospital with a trained personnel cannot be overlooked. Since more than two-thirds of American babies are still delivered in the home, it would be a premature conclusion that the pains of labor and delivery can be completely controlled by the existing armamentarium of medical sciences. The day of the panacea is not yet in sight. However, tremendous strides have been made toward this end in the last four decades. The Old Testament curse of womankind may some day be repudiated in the fulfillment of the New Testament prophecy from *I Timothy 2:15*: "She shall be saved in childbearing if they continue in faith and charity and holiness with sobriety."

"*Divinum est opus sedare dolorem*" (Divine is the work to subdue pain)—so spoke Hippocrates. This still is the challenge to the chemist, the pharmacologist, the obstetrician, and the anesthetist, who are uniting their efforts toward the safe control of pain in childbirth.

807 Spruce Street  
Philadelphia

### Discussion

Dr Benjamin P. Watson, New York City—It is a moot question whether the publicity which things medical get in the lay press today or the hush hush methods of former times do the more good or the more harm. Lay journalism puts its emphasis on sensation, scientific writing on accuracy.

Having recently had some experience with the ferocity of the reporter, hunting in pack in pursuit of its prey, I am in a position to appreciate what Dr Hingson and Dr Edwards had to contend with when they first developed their method. Fortunately, he, the journalist, is quickly satiated and drops the subject as soon as its sensational and emotional appeal is past. Not so with the scientist, he goes on working out details, checking former observations, making new ones, and correlating these so as to present a truer and more accurate picture.

That is what Dr Lull, Dr Hingson, and their coworkers have been doing for us in the past year. As a result, we have had presented to us today a cold analysis of the facts relating to and an evaluation of the results of caudal analgesia in labor.

That this new method of relieving the pains of labor should have been received with such open mind and developed with such enthusiasm in Philadelphia seems almost like an act of expiation for the sins of those pundits of the past, who there so

bitterly opposed obstetric anesthesia when it was introduced nearly one hundred years ago.

No one who has followed the work of our authors, either by direct observation of their patients or by reading or listening to their articles, can have any doubt as to the relief of pain afforded by caudal anesthesia. They further claim that it does not retard but, in most instances, expedites labor, especially in its first stage; that it causes such relaxation of the structures of the pelvic floor that the second stage can be terminated by an easy low forceps traction; that the third stage is shortened; that blood loss is lessened, and that the child is not apneic but cries lustily immediately after it is born. All of these claims I believe they have fully substantiated and they have every right to be enthusiastic.

But their enthusiasm is tempered with caution, and their chief emphasis today is on caution and contraindication.

The cases for it must be carefully chosen; in their experience not more than 60 per cent of private patients and not more than 50 per cent of general clinic patients are suitable. It is, therefore, not something that can be "sold" to every pregnant woman who presents herself in the doctor's office. As in the past, no one can promise a woman a painless labor.

They lay great stress on the necessity for teamwork between the obstetrician and the anesthesia staff. It is not a method to be used casually by the individual. It is necessary to have those skilled in the technic of needle introduction; there must be constant supervision of the apparatus and rate of flow. When things go wrong there must be no delay in applying appropriate remedial measures. The Philadelphia Lying-In Hospital has been fortunate in being able to provide all of these things. Some other clinics, among them the one to which I am attached, have not had the necessary personnel, so our experience has been very limited. When the present emergency is over I believe that every major obstetric department will have a staff trained to carry out the method in the cases suitable for it.

What might be called the side issues of this investigation are of great interest and of real scientific and practical value. The anatomy of the sacrum has been studied on the cadaver and by x-ray, and new facts have been brought to light.

The anatomy of the nerves of the uterus and other pelvic organs has been elucidated. I hope that as a result of the work of our authors I shall be able to teach it to my students in a more satisfactory way than I have done in the past.

The authors' observations on blood pressure and on the effects of caudal analgesia in the eclamptic state hold out great hope for the future.

I congratulate the authors on their scientific approach to this very practical problem in obstetrics.

**Dr. William Levine, Brooklyn, New York**—The authors' efforts to stimulate further research and investigation in uterine neurology and physiology and anatomic variations and malformations of sacra are very laudable. Moreover, their undertaking to teach and train several hundred physicians

to properly and safely administer continuous caudal analgesia is commendable. The results of their tocographic observations are eagerly awaited. Their reported x-ray studies of the anatomic variations of sacral hiatus have already been of great benefit.

As obstetricians we feel indebted to them for their persistence in making this form of analgesia a permanent part of our armamentarium. Efforts to discredit the method because of undue and premature acclaim of "painless birth" by the public press are unfair. This should not deter us from giving the procedure a fair trial in our delivery rooms.

We have used continuous caudal analgesia at the Beth-El Hospital since February, 1943, in 836 patients. We administer 1.5 per cent metycaïne in normal saline and incorporate ephedrine in the solution. Thirteen of these patients had cesarean operations; the remainder were delivered by the vaginal route either spontaneously or by low forceps, midforceps, forceps rotation, manual rotation, breech extraction, or internal podalic version. Most obstetric procedures have been done under this form of analgesia satisfactorily, without supplemental inhalation anesthesia.

The duration of the entire labor is remarkably shortened. Cervical dilatation is very rapid, definitely shortening the first stage. Instances of persistent thick cervical lip remaining for many hours in occipitoposterior position are infrequent. On the average, full dilatation was reached in three and a half hours for primiparas; in multiparas in less than two hours. Descent during the second stage of labor is unhampered and progresses rapidly, but actual delivery in many instances must be accomplished by forceps. We agree with the authors that instances of persistent occipitoposterior position and deep transverse arrest have not materially increased. Operative delivery is facilitated because of the relaxation of the pelvic parts. Repair of pelvic floor lacerations and episiotomy is greatly facilitated.

The third stage of labor has similarly been rapid and with minimal blood loss. Postpartum hemorrhage due to uterine atony was encountered only one time. There were no instances of retained placenta. The routine use of oxytocic drugs may be eliminated, for at the end of labor the uterus remains firm, well contracted, and at or below the umbilicus. Subsequent involution of the uterus and other pelvic structures is satisfactory throughout the puerperal state.

We have had no maternal mortalities or maternal morbidities from this form of analgesia. All newborn infants cried spontaneously immediately after delivery and only few needed any resuscitation. Extensive resuscitation was needed only when traumatic obstetric deliveries caused delay in initiating respiration.

The uterus continues to contract rhythmically throughout labor; therefore, any intrauterine manipulation is inadvisable. Hence, when this procedure is anticipated, as in transverse lie, unengaged frank breech, possible version in a

second twin, placenta previa, abruptio placenta, unengaged head, it should not be administered. It is, however, of decided benefit in patients suffering from heart disease, pulmonary disease, and toxemia of pregnancy.

Short of the above conditions, this form of analgesia is suitable in the great majority of obstetric cases.

In cases in which there is an existing localized infection, sinus, or evidence of an occult lesion or anatomic malformation in the sacrococcygeal region, it is obviously inadvisable to use this form of analgesia. Our experience at the Beth-El Hospital

has been that the above exceptions do not account for 40 per cent of unsuited cases, as stated by Drs. Lull and Hingson.

We urge its adoption to further crystallize its usefulness. We agree that for successful use it needs a setup where facilities are provided for close watching, expert obstetric judgment in its application, and skill in its administration. At present, it is not a method that can be used by individual practitioners in inadequately equipped hospitals nor in home deliveries. To us it seems to be an obstetric analgesic that more closely approaches the ideal than any heretofore in vogue.

### INFANTILE PARALYSIS FIGURES

In the first thirty-one weeks of 1944, the United States had more cases of infantile paralysis reported than at any comparable time shown on the records in twenty-eight years, the National Foundation for Infantile Paralysis has disclosed.

Latest figures from the U. S. Public Health Service, showing state reports through August 5, reveal a total of 3,992 cases. This is 1,226 cases more than reported for the same period last year when the nation suffered its third-worst polio epidemic, and 1,089 cases more than in 1931, when the second-worst outbreak was recorded. The records of the worst outbreak, in 1916, show there were 6,767 cases by August 1 of that year.

In five states where the outbreaks were in epidemic or near-epidemic proportions, the total cases reported through August 5, 1944, are higher than those states reported for the entire year of 1943.

They are:

State	Through August 5, 1944	Entire year of 1943
New York	902	692
North Carolina	470	37
Kentucky	377	157
Pennsylvania	284	143
Virginia	205	61

The serious or threatening outbreaks this year were confined almost entirely to states east of the Mississippi, while last year's were largely west of the river.

Basil O'Connor, president, reported that the National Foundation has sent epidemic aid, in either emergency funds, professional personnel, or supplies and equipment, into thirteen affected states.

In addition to the five states named above, they are: Ohio, Tennessee, Michigan, Mississippi, Indiana, Washington, Oregon, and California. Outbreaks in the latter three states earlier this year

### CRIPPLED CHILDREN GET \$10,000,000

The Association for the Aid of Crippled Children of 580 Fifth Avenue, New York City, will come into a bequest, exceeding \$10,000,000, within the next few months.

Milo M. Belding, a silk-thread manufacturer who died on October 13, 1931, provided in his will that his residuary estate should go to the Association on the death of his wife, who received the income for life. Mrs. Belding died on September 4.

The estate was appraised in 1934 at \$3,819,366 gross and \$3,303,311 net. After a number of bequests to employees, the residuary estate amounted to \$3,107,731.

Mr. Belding had previously, in 1921, erected a trust fund, providing that the income was to go to his widow for her lifetime and that on her death

\$10,331,183, but Thomas S. McLane, treasurer of the Association, said that he understood their present value was somewhat less than that figure.

Mr. McLane said that the Association had not yet decided upon its plans for utilizing the very large sum that will come to it. He said that it would probably be a number of months before the money would become available, and that meanwhile the Association would carry on its normal course.

The association, which has district offices at 1826 Arthur Avenue, the Bronx, and 12-26 Thirty-first Avenue, Astoria, Queens, provides home visiting and health supervision of mentally normal, orthopaedically handicapped children from birth to 16 years, by a specialized staff of graduate nurses.

The enormous expansion that will be made possible by the Milo M. Belding Fund may be judged from the fact that the Association's total expenditures in 1943 were \$93,778. Its receipts last year were \$81,709, leaving a deficit of \$12,069.

January in the celebration of the President's birthday.

# DIAGNOSIS OF DISORDERS OF THE SMALL AND LARGE INTESTINE

EVERETT D. KIEFER, M.D., Boston

THE diagnosis of disorders of the small and large intestine depends largely upon the recognition of significant *subjective symptoms*.

A common complaint, such as constipation, may mean much or very little. If by "constipation" the patient means infrequent stools over a period of many years without serious impairment of health, the complaint is probably either imaginary or functional. If, on the other hand, there has been a recent and distinct change in bowel habits, an organic basis for the complaint must be considered as a probability. It is the change in function which is significant. For example, the unexplained onset of loose stools after lifelong constipation may be hailed by the patient as an improvement but may signify the development of a new growth in the colon.

As a general rule, diarrhea is more likely to signify a real disorder than is the complaint of constipation.

Other signs and symptoms which tend to indicate an organic disease rather than a functional disorder are anorexia, loss of weight, fever, anemia, leukocytosis, pain which is intermittent and severe or interferes with sleep, and blood or pus in the stools. When any of these clinical features exists, a search should be carried on until the explanation is discovered.

The significance of any subjective complaint is better understood if the disturbed physiology that produces it can be identified. Briefly, the functions of the intestine include liquefaction of food material, digestion, absorption, and motility.

While the digestive and absorptive processes are going on, the intestinal contents progress constantly toward the rectum. Consequently, disturbances in motility may affect the other functions of the intestine, and, as a producer of symptoms, disturbed motility outweighs in importance all the other disorders of function.

Intestinal pain is a product of disturbed motility and occurs as a result of abnormal spasm or tension in the intestinal wall. It may be associated with the hypermotility that follows intestinal irritation or with the forceful efforts on the part of the muscularis to overcome mechanical obstruction. Intestinal pain, which may be identified by its intermittent, sharp, cramp-like nature, is referred to by patients as "gas pains." It tends to appear immediately after the intake

of food because it occurs simultaneously with intestinal peristalsis. Pain which occurs just before defecation and is relieved by the passage of gas or a stool usually arises in the colon. Intestinal colic, which causes poorly localized and shifting pain, tends to involve both sides of the abdomen. Since renal colic tends to be localized to only one side, this is a useful differential point. There is usually no radiation to the groin, genitals, or thigh, as may occur in urinary tract pain.

Right upper quadrant pain is common in colon disorders, but radiation into the right subscapular region, so characteristic of biliary colic, is rare. The extension of upper abdominal pain up into the chest, which is often noted with gastric, pyloric, and duodenal spasm, is not common in intestinal colic.

Chronic, persistent right lower quadrant pain, particularly when it is long-standing, is much more likely to be indicative of an irritable cecum than of chronic inflammation of the appendix. Left lower quadrant pain also may indicate a spastic condition of the colon, particularly if it is associated with a palpable, tender, and ropy sigmoid.

The differentiation between small-intestinal and colonic pain is difficult and often uncertain. Pain arising from small-intestinal colic has a tendency to be most intense in the upper abdomen or around the umbilicus. Pain arising in the large bowel usually is felt across the lower abdomen, but may be fairly well limited to any of the four abdominal quadrants or even to the low back.

Nausea, which is a fairly common symptom, occurs simultaneously with the intestinal colic. If the pain is severe, there may be vomiting. Nausea and vomiting are apparently due to reflex action upon the stomach, since they frequently occur in the absence of mechanical obstruction. Of course, when obstruction exists, particularly at a high level, vomiting is much more prominent.

The character of the stool also is controlled largely by the motility rate in the intestinal canal. The content of the small intestine enters the cecum in a liquid state, but as it passes over to the sigmoid there is constant absorption of water with the result that the liquid is changed to a soft solid mass. A liquid or abnormally soft stool indicates hypermotility of the colon, with insufficient time for water absorption; on the other hand, a hard dry stool indicates too slow passage of the stool through the large bowel. Therefore, when a patient complains of either constipation or diar-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944.

From the Department of Gastro-Enterology, Lahey Clinic, Boston.

rhea, one should determine the consistency of the stool before forming an opinion of the actual motility of the colon.

Colonic motility is dependent partly upon the function of the small intestine. The large bowel action may be slowed by diminished flow from the ileum as a result of reduced food intake or other causes, or it may be accelerated by hypermotility of the small bowel. The clinical importance of this is that diarrhea may be a symptom of small-intestinal disease.

Intestinal motility, particularly in the small intestine where practically all digestion and absorption take place, also may affect other functions of the digestive tract. In acute or chronic inflammation or irritation, a small-intestinal diarrhea occurs which does not permit adequate absorption. In consequence, the stools contain abnormal amounts of unabsorbed protein, carbohydrate, fats, and vitamins, and malnutrition naturally follows.

Other information concerning the gross characteristics of the stool is usually available through the history. The presence of mucus, which may be a matter of great concern to the patient, really means very little except increased irritability of the colon or a neurogenic overactivity of the mucus producing glands.

Gross blood, on the other hand, is always significant. It should never be ignored and its source should always be determined.

The physical findings in intestinal disorders often are provocative to further study without being actually diagnostic. This is true of all signs of malnutrition, blood loss, abdominal tumors, distended intestinal loops, and visible peristalsis. Errors in physical diagnosis are much too frequent and are chiefly errors of omission. Since a high percentage of rectal cancers are within easy reach of the examining finger, many tragic delays would be avoided if the rectal examination were considered an indispensable routine.

Another office procedure by which the diagnosis often can be established is the proctoscopic examination of the rectum and lower sigmoid. The proctoscope is a simple instrument, safe and easy to use, and serious errors are uncommon even in inexperienced hands. This instrument, which should have a place in every general practitioner's equipment, provides a direct inspection of the interior of the rectum by which tumors, ulcerations, and inflammatory changes in the mucosa readily may be discovered. The most important service rendered by the proctoscope probably is the elimination of the diagnostic "blind spot" at the rectosigmoid juncture. Lesions at this point, which often are just beyond the reach of the examining finger, are notoriously difficult to demonstrate by roentgenologic examination.

The only safe procedure is to perform a proctoscopic examination on every patient with rectal bleeding. The source of bleeding usually can be determined, and even when no lesion is seen, blood coming from above the reach of the instrument is positive proof of an organic lesion.

Diarrhea is another indication for proctoscopic examination. Changes in the mucosa may be identified, and a specimen of stool or exudate may be obtained for immediate microscopic examination and culture.

The roentgenogram plays an important role in the diagnosis of intestinal disorders. With the exception of patients suspected of having low-bowel obstruction, a barium meal with films taken at suitable intervals to show the small intestine and cecum, followed in twenty-four hours by a barium enema, yields the most conclusive findings. The small bowel is best studied by films taken at hourly intervals for a period of six hours after a barium meal. The serial films reveal small intestinal motility, obstruction, dilatation, and changes in the caliber, flexibility, and mucosal pattern.

Certain limitations of roentgenologic diagnosis must be kept in mind. Since narrowing of the lumen of the small bowel may cause no delay until obstruction is almost complete, intermittent small-intestinal obstruction, particularly when caused by bands of adhesions, may not be evident roentgenologically unless the examination is made in the presence of symptoms of obstruction. In suspicious cases, if possible the patient should be examined during an attack even if only by a plain film of the abdomen, in the upright position, so as to show fluid levels in the distended loops.

### Case Reports

Some of the more important points in roentgenologic diagnosis are illustrated in the following cases.

**Case 1**—A woman, 26 years of age, complained of bloody diarrhea of ten months' duration. At times she had fifteen stools a day. She was extremely nervous and had lost 40 pounds in weight. The appetite was poor. There had been no remission or relief in spite of treatment for ulcerative colitis.

There was no abdominal mass. The digital examination of the rectum was normal. Proctoscopic examination revealed a cauliflower like lesion with a central crater characteristic of adenocarcinoma at the rectosigmoid juncture. A barium enema was attempted but the barium could not pass beyond the rectosigmoid.

The diagnosis of adenocarcinoma was confirmed by operation and tissue examination.

While the clinical picture of this case strongly

FIG. 1. Barium enema showing a long, obstructing filling defect in the sigmoid, produced by an inflammatory mass arising from diverticulitis.

FIG. 2. Barium enema showing a filling defect in the cecum caused by adenocarcinoma.

suggested ulcerative colitis, if the following four axioms had been observed, the error in diagnosis would have been avoided.

1. Cancer of the rectum or intestine may occur at any age.

2. The source of blood in the stool always must be determined.

3. The diagnosis of ulcerative colitis should not be made without direct visualization of the pathologic changes in the mucosa by proctoscope.

4. The roentgenogram is not entirely reliable in ruling out lesions in the rectum or rectosigmoid.

*Case 2.*—A woman, 75 years of age, complained of a mucopurulent rectal discharge of six months' duration. For twenty-five years at intervals of two or three months attacks of lower abdominal pain, diarrhea, and vomiting had occurred. During the last ten months a persistent diarrhea had developed. Her appetite had failed, and she had lost weight and strength.

Except for moderate emaciation, the physical examination was not revealing. There was no fever or mass in the abdomen. The rectum was normal by digital examination and by proctoscope, but it was impossible to pass the proctoscope beyond the rectosigmoid because of fixation of the bowel. The

blood examination showed a moderate anemia and a normal white cell count. The barium enema showed an obstructing organic stricture of the sigmoid (Fig. 1).

In the differential diagnosis of this type of case, cancer of the sigmoid should be considered first, and about the only other possibility is diverticulitis. The anorexia, anemia, and weight loss certainly suggested carcinoma, but the absence of blood in the stools and the mucopurulent discharge favored inflammatory disease. The roentgenologic picture could be produced by either condition, but certain features, such as the length of the deformity and the fusiform shape of the ends of the defect, instead of a hooking over of normal bowel wall, were in favor of an inflammatory mass.

The diagnosis of diverticulitis was confirmed at operation.

*Case 3.*—A woman, 43 years of age, complained of right abdominal pain occurring at irregular intervals for four years. She had had three attacks of severe abdominal pain. Her appetite was normal, but she had lost 9 pounds. After taking castor oil she had had a loose stool containing some red blood.

Examination revealed a definite pallor and a palpable mass in the right lower quadrant. The blood

FIG 3 Barium enema showing an annular filling defect in the sigmoid. Diagnosis: Carcinoma of the sigmoid.

FIG 4 Roentgenogram of the colon showing a large mucosal polyp in the descending colon.

examination showed a moderately severe anemia. The roentgenogram of the upper gastrointestinal tract was negative except for dilatation and delay in the lower ileum (Fig 2). Roentgenologic examination by barium enema showed a discrete filling defect innervating the cecum at the ileocecal valve.

The diagnosis of carcinoma of the cecum was confirmed by operation.

This case illustrates the occurrence of a serious lesion in a relatively young person with vague and rather chronic abdominal symptoms, and emphasizes the value of a complete study in any person of middle age who complains of a change in digestive functions. Lesions of the cecum are often "silent" except for the anemia which is so characteristic of cancer of the right colon. This is true because obstruction is a late development because of the large caliber of the lumen and the fluid content of the bowel which permits the growth to become relatively large before pain occurs. In the presence of severe anemia, cancer of the right colon should be considered even though abdominal symptoms are absent or minimal. In this case obstruction at the ileocecal valve produced small intestinal obstruction and colic.

**Case 4**—A man 67 years of age complained of lower abdominal pains. He had always had constipation and had taken laxatives all his life, but for three months he had had sharp cramp-like pain and

bloating of the lower abdomen and increasing difficulty in bowel function. His appetite was almost normal. He had lost 5 pounds.

The physical examination was not revealing, and the rectal examination was negative. The blood showed a slight anemia. Roentgenologic examination by barium enema showed an annular filling defect in the sigmoid (Fig 3). Diverticula were also present.

The diagnosis of carcinoma of the sigmoid was confirmed by operation.

This case illustrates the significance of a change in bowel habits and the importance of diagnostic study. The differential diagnosis was between carcinoma and diverticulitis. Even though diverticula were present, the roentgenologic defect was more characteristic of carcinoma than of an inflammatory lesion. The typical "hooking" deformity is caused by the sharp demarcation between normal and rigid bowel wall, such as occurs in annular new growths, while in granulomas of the bowel the transition between rigid and normally flexible intestinal wall is not sharply demarcated and the narrowing is gradual.

This patient's symptoms obviously were caused by progressive obstruction which occurred early in the development of the growth because of the solid nature of the intestinal content when it reaches the sigmoid.

**Case 5**—A girl, 4 years of age, had had generalized

Fig. 5. Roentgenogram of the colon with double contrast technic showing a polyp in the sigmoid.

abdominal pain associated with the passage of bloody stools for two months. The stools sometimes consisted almost entirely of red blood. There was no fever and the child's general health appeared to be normal.

The physical examination was negative. Blood examination showed no anemia. The proctoscopic examination was negative, except for blood coming from a level higher than could be reached with the proctoscope. Roentgenologic examination by barium enema showed a rounded filling defect in the descending colon (Fig. 4).

The diagnosis of a mucosal polyp was confirmed by operation.

The most common symptom of a single benign polyp of the colon and rectum is bleeding. With a tumor as large as this, intermittent attacks of intussusception with severe pain are likely to occur.

The visualization and identification of small intraluminal tumors of the colon may be aided by the use of the double contrast technic, or air enema, in which the colon is distended with air after just sufficient barium has been introduced to cover the mucosa.

Fig. 5, a roentgenogram of a double contrast enema in another case, demonstrates a barium-covered polyp projecting into the lumen of the sigmoid, which is distended with air.

*Case 6.*—A man, 37 years of age, complained of

Fig. 6. Roentgenogram of the colon in chronic ulcerative colitis shows loss of haustral markings and ragged irregular outline caused by ulcerations, and fibrotic changes in the bowel wall.

chronic diarrhea of five years' duration. For two years before the onset of diarrhea he had noted frequent rectal bleeding. The attacks of diarrhea, which had increased in frequency and duration, were brought on by respiratory infections, overwork, and emotional upsets, and at times were accompanied by some fever. He frequently noted blood in the stools, which were watery and often consisted of only a small quantity of blood-tinged mucopurulent exudate. Six to eight stools usually occurred during the day and two or three at night. There had been a gradual loss of 50 pounds in weight.

On examination the patient was pale and emaciated. There was no abdominal tumor. The blood showed a marked hypochromic anemia. The proctoscopic examination revealed a contracted lumen of the rectum and sigmoid and changes in the mucous membrane characteristic of ulcerative colitis. There was considerable mucopurulent exudate which on microscopic examination showed numerous leukocytes and red blood cells but no amebae. Roentgenologic examination of the colon by barium enema showed a diffuse generalized loss of haustral markings, contraction in the length and caliber, loss of flexibility, and changes in the mucosal pattern (Fig. 6).

The diagnosis was chronic ulcerative colitis.

The insidious onset of diarrhea, rectal bleeding, or both is characteristic of ulcerative colitis.

The recurrent bouts and remissions are more suggestive of colitis than of malignant disease of the bowel. The conclusive diagnosis, however, depends upon the characteristic roentgenologic and proctoscopic findings, which may be somewhat variable, depending upon the severity and duration of the disease.

Acute severe ulcerative colitis is characterized by marked spasm, which prevents complete filling of the bowel with the barium enema. There are also typical changes in the mucosal pattern, which are shown best in the descending colon.

**Case 7.**—A man, aged 52 years, complained of diarrhea of four years' duration and recent rectal tenesmus. There were six to eight watery stools a day. Streaks of blood and mucus often were seen. He had been able to work and had not lost weight. He gave a history of amebic dysentery twenty years previously while in Egypt, with subsequent spells of diarrhea at long intervals.

The physical examination was negative. The blood was normal. The proctoscopic examination revealed a small amount of serous bloody fluid in the rectum. The mucosa was thickened, inflamed, and ulcerated in some areas and practically normal in others. A small drop of fluid was removed from the rectum, mixed with normal salt solution, and examined under the microscope. Many motile amebae containing red blood cells were seen.

The blood examination showed a slight anemia. Roentgenologic examination by barium enema showed diffuse spasm of the colon but no diagnostic organic changes. Injections of emetine were given intramuscularly, and with the first injection the rectal tenesmus was relieved and the bowel function became normal within a few days.

The diagnosis was amebic dysentery.

This case illustrates the following important points in the diagnosis of amebic dysentery:

1. The disease may be encountered in any climate.
2. It may remain latent for a long time.
3. The proctoscopic findings may not be diagnostic, but the areas of normal mucosa interspersed with areas of inflammation and ulceration are highly suggestive of amebiasis instead of chronic ulcerative colitis, in which the mucosa is diffusely involved with no areas of normal mucous membrane.
4. The proctoscope provides an easy method of obtaining a suitable specimen for immediate microscopic examination, which is the conclusive diagnostic test in this disease.
5. The therapeutic test with emetine is sometimes striking.

The motile phagocytic form of the pathogenic ameba is found in the rectum or in the stools only in the presence of diarrhea or following catharsis. Patients with chronic amebiasis without diarrhea

Fig. 7. Roentgenogram of the small intestine showing a dilated loop of jejunum proximal to an annular defect produced by carcinoma of the jejunum.

may have only the encysted forms of ameba in the stools.

**Case 8.**—A man, 46 years of age, complained of intermittent attacks of extremely severe cramp-like upper abdominal pain accompanied by vomiting. These attacks had occurred about once a month for four months. He was known to have a chronic duodenal ulcer, but the presenting symptoms were different from all previous ulcer distresses.

The physical examination was negative. The blood was normal. Roentgenograms at hourly intervals after a barium meal showed a dilated loop of jejunum in the lower abdomen. At the distal tip of the dilated loop there was a cuff-like deformity characteristic of intussusception.

The diagnosis of small intestinal tumor with intermittent obstruction was confirmed by operation. The pathologic diagnosis was tuberculoma of the ileum.

This case is illustrative of the typical symptoms produced by small intestinal tumors, particularly benign tumors which are not fixed. Severe pain occurs in the upper or midabdomen and lasts for several hours. Between attacks there are no symptoms. Intermittent intussusception with obstruction is produced by the peristaltic action upon the tumor which forces it downward into the lumen of the lower loop, dragging with it the upper loop to which it is attached.

**Case 9.**—A man, aged 31 years, complained of acute attacks of severe, cramp-like upper abdominal pain lasting several hours and accompanied by vomiting. The attacks had occurred at intervals of sev-

FIG. 8. Roentgenogram of the small intestine showing a large irregular cavity in the jejunum as a result of neurofibrosarcoma.

eral weeks over a period of nine months. Between attacks he was perfectly well. Two years before, a subtotal gastric resection for chronic duodenal ulcer had been performed.

The physical examination was negative. The blood and urine examinations were normal. Gastrointestinal roentgenograms, including several films of the small intestine, were negative. The patient was advised to have a plain film of the abdomen in the upright position during the next attack. This showed dilated loops of small intestine in the right lower quadrant with fluid levels. Another barium series showed delayed motility and dilatation of the small intestine.

The diagnosis of intermittent small-intestinal obstruction was confirmed by operation, which disclosed obstructing adhesions involving the upper ileum, which was adherent to the abdominal wall.

*Case 10.*—A man, aged 61 years, complained of generalized cramp-like abdominal pain and vomiting of six weeks' duration. The ingestion of food caused pain and vomiting. Although the appetite was good, he had eaten and retained very little, with the result that he had lost 40 pounds in weight.

The physical examination was negative. The blood examination was normal. The stools were strongly positive for occult blood. Roentgenograms of the gastrointestinal tract after a barium meal showed an annular constriction in the jejunum with dilatation of the bowel above this point (Fig. 7). There was "hooking" of the barium column around

FIG. 9. Roentgenogram five hours after a barium meal, showing the typical narrowing and mucosal changes of the ileum in a case of regional ileitis.

the stricture. Barium was retained in the small intestine for twenty-four hours.

The diagnosis of carcinoma of the jejunum was confirmed by operation.

This annular malignant tumor was symptomless until the gradual narrowing of the lumen produced an unrelenting obstruction without intussusception.

Although the presenting symptom of malignant disease of the small bowel is usually obstruction, there are some malignant tumors which produce ulceration and cavitation without obstruction, in which case anemia and cachexia are the most prominent features.

*Case 11.*—A man, aged 37 years, complained of weakness and anemia of ten years' duration. The anemia was extremely severe and was getting progressively worse, requiring several transfusions. He had some vague abdominal distress but no severe pain or vomiting. In recent months there had been some fever, and the spleen was enlarged.

The patient was subjected to extensive study in the hospital to determine the nature of what appeared to be a blood disease. The stools contained occult blood, and after several transfusions he had a hemorrhage into the intestinal tract. Gastrointestinal roentgenograms, including films of the small intestine, showed a marked deformity, apparently a large irregular cavity in the lumen of the jejunum (Fig. 8).

A diagnosis of an ulcerating tumor of the jejunum was made. Operation revealed a neurofibrosarcoma arising in the retroperitoneal region near the ligament of Treitz, with ulceration into the jejunum.

*Case 12*—A woman, aged 24 years, complained of generalized cramp like abdominal pain of four months' duration. The pain was sharp, occurred daily, and was brought on by meals. It was accompanied by vomiting and diarrhea of from four to eight stools a day. She had lost about 50 pounds in weight.

The physical examination was negative. There was no fever. The blood examination showed slight leukocytosis. The proctoscopic examination was negative except for a soft foamy stool in the rectum. The stool cultures and microscopic examinations were negative. Serial roentgenograms of the small intestine after a barium meal showed delay and dilatation with rigid narrowing of the terminal ileum (Fig. 9).

The diagnosis of advanced terminal ileitis with obstruction was confirmed by operation.

This is a case of diarrhea and abdominal pain caused by disease limited to the small intestine. The roentgenologic evidence of chronic ulcerative enteritis is variable, depending upon the severity of the disease, its extent and distribution, and the stage of the pathologic process.

In terms of incidence, the acute gastrointestinal upset, characterized chiefly by diarrhea and commonly known as "intestinal flu," ptomaine poisoning, and summer complaint, is an important clinical entity.

*Case 13*—A man, aged 38 years, complained of diarrhea and malaise, which began five days previously with a chill, temperature of 103 F., and diarrhea. Nausea, weakness, and generalized aches and pains were present. On admission the diarrhea had subsided to five or six stools a day.

The physical examination was negative. The temperature and blood examination were normal. The proctoscopic examination showed a normal mucous membrane. Stool culture showed no pathogens. Widal and agglutination tests for dysentery were negative.

The diagnosis was acute enterocolitis. With bed rest, a bland diet, and sulfaguanidine therapy, all symptoms disappeared in three or four days.

This case is an example of one of a number of intestinal disorders which may be grouped under

the heading of acute diarrheal disease. Sporadic cases appear in the practice of every general practitioner and epidemics are common, particularly in institutions and camps. While the disease as it occurs in the adult is not usually dangerous, in the infant or young child it often is a serious threat to life.

A clinical and causative classification of the diarrheal diseases has been prepared by Hardy and Watt.<sup>1</sup>

The first group, called primary infectious diarrhea, includes the dysenteries caused by pathogens which establish themselves and grow in the enteric tract. These include bacillary dysentery, acute amebic dysentery, food infection, cholera, other bacterial infections, and parasitic diseases.

The second group, called parenteral and secondary diarrhea, includes those cases in which the intestinal disorder is simply a symptom of a remote disease, such as an acute respiratory or generalized infection.

The third group, called noninfectious diarrhea, includes food poisoning, sewage poisoning, nutritional diarrhea, and allergic diarrhea.

The diagnosis of acute enterocolitis often, of necessity, covers a number of causative possibilities. It is based chiefly upon the clinical features, such as the acute onset, the short duration, and the prominence of general systemic effects with coryza, malaise, vomiting, prostration, and fever. The differential diagnosis of acute enterocolitis can be made only by the isolation from the stools of the specific causative agent, but in a considerable percentage of these cases the cultures are negative. Also, agglutination tests with the patient's serum are too unreliable to be of much value. The important consideration in cases of this kind is that acute enterocolitis should clear up within three to four weeks, and if it does not, a thorough study for other forms of intestinal disease is indicated.

It is beyond the scope of this paper to cover more than a few of the most common disorders of the intestine. However, the same diagnostic principles apply in part, at least, in the diagnosis of any of the rare forms of intestinal disease.

#### KENNY INSTITUTE DRIVE WILL SEEK \$1,702,000

A nation wide campaign to raise \$1,702,000 to make the Sister Elizabeth Kenny treatment of infantile paralysis available to all victims will be conducted from November 13 to 25. This was announced by Marvin L. Kline, president of the Kenny Institute and Mayor of Minneapolis, on September 25.

The fund also will be used for training of technicians, clinical research on paralysis and other neuromuscular disorders, and extension of the Kenny method to other nations, Mr. Kline said.

by Mr. Kline to dis-

Institute

MAC F. CAHAL, J.D., Chicago

ANY casual reader of medical literature and the writings of political economists during the past ten or fifteen years cannot fail to be aware of a growing demand, throughout the world, for improvements in the distribution of medical services. New economic theories and the increasing exigencies of society have created currents within and about the medical profession that are testing its very foundations. It seems unlikely that the system of medical practice as we have known it in this country will be left unchanged when the currents subside. The powerful social forces and the evidences of intraprofessional unrest currently being manifested in the United States can be observed in all the English-speaking nations on the globe.

It is not my purpose here to discuss the question of socialized medicine or the fundamental issues involved in the social economics of medicine, important and interesting as that subject may be. I would emphasize, however, that all the problems created by change and adjustment in the economics of medicine have origins that touch these basic issues. The problems of radiology should be viewed in their relation to the problems confronting all medicine. And we should never forget that the profession of medicine owes its existence to the service it renders the sick. In examining the problems confronting practitioners of the specialty of radiology, therefore, we should not lose sight of the fact that principles espoused by medicine are tenable only so long as their ultimate objective is to improve the standards and quality of medical care for the consequent benefit of the public health.

Among the many factors contributing to the unsettled state in which medicine finds itself today, there is one which holds special significance for radiology. I refer to the unmistakable trend for hospitals to expand their functions and to assume more and more responsibilities in the delivery of medical services. This particular subject has been my special interest for most of the past ten years. It is my earnest conviction that the issues must be squarely faced by both hospitals and doctors and that agreement must be reached upon certain fundamental principles if we are to avoid the grave harm that continued controversy will bring to the interests of both parties, as well as to the public welfare.

Whether deliberately or not, current tendencies

on the part of hospitals find their keynote in the first recommendation made by the Committee on the Costs of Medical Care. In 1932, the Committee recommended that medical care be furnished by groups organized around a hospital. Thus, the hospital becomes not merely a specially equipped institution where doctors may administer to the sick, but a distributing agency for medical care. The hospital itself enters the practice of medicine through the medium of employed agents.

Official statements appearing in the hospital literature from time to time in recent years give conclusive proof that this is exactly the conception of the hospital's function to which many leaders in the hospital world adhere. From scores of similar statements, I quote the following examples.

"Provision of medical services in the hospital is part of the responsibility of the hospital."

"Diagnosis, treatment, and care of the ambulatory sick become increasingly the function of the hospital, as the hospital develops into the center of community health activities."

"From the standpoint of logic, common sense, and welfare of the public it is clear that hospitals should be permitted to practice medicine as they have for many decades."

Now, without pausing to debate the merit of such arguments here, it should be noted that the medical profession has, with considerable emphasis, expressed an opposite view. Taking cognizance of the gradual trend toward the institutionalization of medicine through the encroachments of hospitals, the Judicial Council of the American Medical Association in 1936 issued a strong statement to the effect that:

"It would seem that in this time of extensive changes in hospital economics the point had arrived at which further marriages between hospitals and staff physicians that make the doctor of medicine the servant of the hospital should be stopped, and a series of attempts at divorce among marriages that have already taken place should be instituted. It is not an impossible task but will need a militant local and national ethical spirit behind it and a frowning on those individuals in the profession who, on personal grounds, do not object to the gradual subjugation of the medical profession in the growth of hospital domination."

Summing up a series of similar pronouncements adopted year after year by the American Medical Association, the House of Delegates last year adopted a recommendation that "The House em-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944.

phically reiterate that it disapproves the injecting of a third party into the personal relationship of the patient and the physician, and that hospitals should not be permitted to practice medicine."

And to clear up any doubt about what it meant by this statement, the House went further to say that "The practice of radiology, pathology, and anesthesiology is the practice of medicine just as much as is the practice of surgery or internal medicine and it is only a short step from including the first three in a hospital service plan to including the whole field of medicine in such a plan."

Everyone knows that the reaction of hospitals to such unequivocal demands has been one of polite indifference. There has been no visible reluctance on the part of hospitals to assume more rather than fewer prerogatives as a purveyor of medical care. The number of strictly medical services performed by hospitals has certainly increased rather than diminished.

Are we, then, to accept as correct the prediction of Arthur J. Altmeyer, chairman of the Social Security Board, that hospital superintendents will, in the future, sit at the head of medical groups which practice medicine for and under the domination of hospitals? At the last annual meeting of the American Hospital Association Mr. Altmeyer expressed the opinion that

"We can be confident that in the future, even more than in the past, the hospitals will be the center of coordinated services for the well and for the sick, a community center for prevention as well as for diagnosis and cure. Coordinated with clinics and health centers for those who do not need bed care, working in effective relations with the community wide facilities of the public health agencies and interlocked with the educational institutions of the universities and medical schools, the hospital of today is the health center of the future. There are new and larger opportunities ahead for the hospital administrator."

"Those who would make of the hospital a building in which to furnish bed, board, nursing, and only technical services, and who propose to separate professional services from hospital care, are flying in the face of experience and progress. They would not merely stop the clock—they would turn it back. Their view cannot and should not prevail."

Certainly, if we are not to delude ourselves, we must admit that the trend is in the direction described by this observer. It is said that trends are changed by the will of men, but we would be naive to deny that hospitals are in an enormously powerful position. As the result of technical advancements in medical practice during the past several decades, hospitals are today in the position of controlling the capital plant which modern medicine requires. Hospitals are gradually

becoming the employers and doctors the employees in a system of medical practice that assumes some of the characteristics of big business in contrast to the traditional characteristics of an individualistic profession. The signs are unmistakable. The trend has so far progressed that there are many people today who go to a hospital when they are sick instead of to a doctor.

Now, I have so far endeavored to review some historical developments during which there has occurred a radical change in the functions of the hospital, without assuming that the change is either good or bad. That is a question which I am not prepared to answer. The social concepts involved are so profound, the forces at work are so powerful, the scientific factors so complex, that one cannot categorically say at this time that the centralization of medicine within the administrative framework of a corporate hospital is inherently or inescapably bad. I think that it is bad and that such a system would not long be tolerated by the majority of the American people. I believe that the interjection of a third party between doctor and patient, whether that third party be a political bureau, a commercial corporation, or a charitable hospital, creates a divided loyalty and a difference of purpose that is not to the best interests of the patient. The great majority of physicians are of a similar philosophy. Only time and the decrees of society will determine whether their views or the views of those who advocate the practice of medicine by hospital corporations through groups of salaried physicians shall prevail.

Of one thing, however, I am absolutely certain. I entertain no doubt that the addition of the insurance principle to this kind of practice would result in a type of medical care that would be egregiously bad. One has only to examine the disgraceful conditions which characterized the old "lodge practice" to find abundant proof of the fact that the sale of employed physician's services on a prepayment basis invites abuses that tend to destroy the value of the doctor's services.

This brings me to a consideration of group hospitalization, because, by insisting upon the inclusion of certain medical services among the benefits guaranteed by the Blue Cross, hospitals are repeating the errors committed in the past by those

ing objection of the medical profession to any sickness insurance plan in which benefits in kind are furnished by salaried agents.

Organized medicine has never opposed group hospitalization insurance. It has steadfastly condemned all insurance plans which guaranteed the services of employed doctors as a benefit in

kind to subscribers. Repeatedly the American Medical Association has demanded that the services included in Blue Cross plans be confined to hospital care and accommodations. There is a compendium of resolutions adopted by the House of Delegates of the American Medical Association since 1931, filling more than ten crowded pages, objecting to the inclusion of any type of medical care in Blue Cross benefits. The result, as you all know, has again been an attitude of polite indifference.

In 1937, the Medical Society of the State of New York adopted a set of principles to govern hospital groups in the creation of prepayment plans for hospital care. This Society defined hospital care as "provision of bed, board, general nursing service, customary surgical dressings and medicines, and other facilities of the institution, not including medical care." Then, to leave no room for doubt, the Society defined medical care as "any procedure or service by a licensed physician." Hospitals were requested not to "implicate themselves with conditions inconsistent with the principles and definitions herewith stated."

On June 21, 1939, in view of the open disregard of this request by the Associated Hospital Service, representatives of the county medical societies in the metropolitan New York area issued a joint statement objecting to the inclusion of radiology and pathology among the benefits furnished by the Associated Hospital Service.

On June 9, 1943, the House of Delegates of the American Medical Association adopted the recommendation of its reference committee that "The practice of radiology, pathology, and anesthesiology is the practice of medicine just as much as is the practice of surgery or internal medicine, and that it is only a short step from including the first three in a (hospital) service plan to including the whole field of medicine in such a plan." And, on the same date, the House of Delegates once again emphatically and unequivocally demanded that radiology and pathology be excluded from group hospitalization benefits.

On July 19, 1943, the Associated Hospital Service of New York announced that benefits were being extended by offering complete x-ray examinations without limitation, and complete pathologic service.

Thus, we are provided with rather convincing proof of the fact lamented by the A.M.A. House of Delegates when it said last year "That the Blue-Cross plans to give medical service with or without the approval of the medical profession."

This is unfortunate. Blue Cross is never going to enjoy the growth it seeks until it wins the approval and support of the medical profession. That approval and support will be forthcoming

when, and only when, the services of all physicians are excluded from the service benefits which hospitals guarantee to provide subscribers in their contract with the Blue Cross.

Hospital spokesmen present three arguments to justify their open disregard for the expressed wishes of the medical profession in this matter:

1. Most radiologists, pathologists, and anesthesiologists, they say, are employees of the hospitals in which they work; hence it makes little difference whether the hospital collects for their services from the individual patient or from an insurance corporation.

2. The plan cannot be sold unless these special services are included.

3. Patients customarily regard radiology and these other services as a part of their hospital care and would object if they were not covered with their hospital bill.

Now, the last of these arguments, unfortunately, is difficult to deny. Whether we like to admit it or not, the fact is that patients have come to regard a hospital x-ray examination as a function of the hospital. Indeed, many patients, when discharged from a hospital, are not aware that they have received the services of a medical specialist when they pay for an x-ray examination along with their hospital bill.

But the solution is not to perpetuate this improper condition. It should be corrected, and it will be corrected if hospitals will cooperate in following the recommendation of the American College of Radiology that charges for x-ray services in the hospital be collected in the name of the physician rendering the service.

The first and second arguments are thoroughly specious. The fact that a considerable number of radiologists are in the legal position of employees of their hospitals is completely beside the point of issue. The issue is not whether they are employed servants of the hospital, but whether their services shall be sold on a prepayment basis to several million potential patients. Contrary to the familiar claims of Blue Cross directors, a radically new factor is imposed upon existing arrangements when hospitals contract to deliver the services of their radiologist to insured subscribers for a fixed per diem rate from the insurance corporation. This type of practice has been condemned by the medical profession for more than thirty years, and I dare say there will be no retreat from its strenuous opposition. True, doctors contract to provide benefits in service when they participate in medical service plans, now being so energetically promoted by medical societies. But in medical service plans the doctor is the insurer; in hospital service plans which include medical benefits a third party, the hospital, is the insurer. The difference is profound.

The second argument is even less sound. Blue Cross can be sold without including radiology. More than half the approved plans in the country have acceded to the demands of the medical profession by confining their benefits to strictly hospital services, they enjoy the approval and support of their local medical societies, and seem to be doing very well.

Nevertheless and notwithstanding, some of the larger plans, including the Associated Hospital Service of New York, which alone accounts for one tenth of the total national enrollment, continue to disregard the principles and the entreaties of the medical profession. An unrelenting battle has been carried on here for nearly ten years, during which the Blue Cross plan has continuously refused to comply with standards set up by national, state, and local medical bodies.

Well, where does that leave us? Hospitals and doctors have apparently reached an impasse over divergent principles. Let me emphasize here that the issue concerns the principle at stake. The inclusion of radiology as a hospital benefit in Blue Cross is not the important issue, it is the precedent which will be established by sacrifice of the principle and its implications for all of medicine that is important.

Already there is evidence of what this precedent will mean to future generations of doctors. In the Federal program of obstetric and pediatric care for enlisted men's families, radiology is included among the hospital services to be provided for a fixed per diem rate. Proposals for the care of World War II veterans in private hospitals contemplate x-ray services as part of the care for which hospitals will be reimbursed under an inclusive fee. The Wagner-Murray-Dingell bill defines hospital care as including x-ray services, all to be furnished for a fee not exceeding \$6.00 per day. (Incidentally, the British White Paper recently submitted to Parliament by the Minister of Health regards radiology as a part of hospital care.)

Let us consider for a moment the profound implications which this question possesses for other medical specialties. Blue Cross plans are currently preparing to embark upon programs offering complete medical or surgical care in addition to hospitalization. The proposal is to pay cash benefits to participating physicians and surgeons. But if a hospital can collect from the insurance corporation for the services of a radiologist, what is to prevent it from restricting its staff to salaried surgeons and collecting from the insurance corporation for their services?

Unfortunately, in the State of New York, nothing would. A considerable amount of loose talk has been indulged in by various hospital administrators in this area who have essayed to

settle the legal issues involved in relations between doctors and hospitals. Mostly they have proved nothing more than that law is better understood by lawyers than by doctors or hospital superintendents. But the fact is that the New York Court of Appeals, in interpreting the statutes of this State, has ruled that hospitals are not subject to the common-law prohibitions against the practice of medicine by corporations.

The courts, therefore, offer no remedy to radiologists who object to the ancillary position to which Blue Cross would relegate them. But they are not without remedy. Several alternative steps merit consideration.

In the first place, radiologists should not delay efforts to arrange for the collection of charges for x-ray examinations performed in the hospital in the name of the physician rendering the service. I have already stated that this has been recommended by the American College of Radiology. It is also consistent with principles promulgated by the American College of Surgeons and the American Medical Association. If, instead of seeing an item "x-ray" on his hospital bill, a patient finds a charge for "x-ray examination by Dr. Blank and consultation with Dr. White (the attending physician who ordered the examination)," he will not assume that x-ray services are part of hospital care, and Blue Cross could no longer justify inclusion of radiology on this ground.

The growth of medical service plans offers, in my opinion, the most promising opportunity for divorcing radiology from hospital care and placing it with medicine, where it belongs. If the medical or surgical care plan includes radiology among the services provided, there will be no justification for retaining it as a benefit in Blue Cross.

Or, if this is not possible, a desirable compromise might be reached here as it was in the State of Washington, where Blue Cross pays cash benefits on a fee basis for radiology. I have been informed by the director of the Hospital Service Commission of the American Hospital Association that the separation of radiology from hospital care in this manner would meet with the approval of the hospital association.

There is yet another step, which I hesitate to mention, but which sometime in the future may be forced upon radiology, and perhaps other branches of medicine. I hope that the doctor can adjust his principles to the forces of social and economic change without divesting himself of the priestly robe which is his tradition. But it is not inconceivable that we shall live to see the day when doctors turn to the union as a means of protecting their standards and their welfare. If the bulk of the population becomes enrolled in

a plan, either voluntary or compulsory, in which radiology is treated as a part of hospital care and all radiologists thus become virtual hirelings of hospitals, which retail their services on an insurance basis, the technics of organized labor may provide the only means available for preservation of their principles. Within the past six months a national association of doctors has been formed for the purpose of pursuing union methods. At least one state medical society has seriously proposed that the A.M.A. affiliate with organized labor.

Of course, medicine can never utilize the strike as a means to gain its ends, but, if radiologists were organized in a union, the controversies raised by their relations with hospitals would be very swiftly resolved. Of that you can be sure.

Please do not misunderstand me. I am not here making a proposal. I am utterly sincere in my belief that no principle of medicine is worth preservation unless it is founded upon considerations that place the public welfare above the welfare of doctors. I mention this alternative merely as a not inconceivable eventuality.

At the opposite extreme I would mention another suggestion that has occurred to a number of sound thinkers in radiology. Dr. B. R. Kirklin, for example, in speaking before an American College of Surgeons meeting some years ago, considered the desirable results that would follow a reduction in fees charged by radiologists.\*

There is no denying that current agitation for radical innovations in our system of medical care is largely engendered by the alleged high cost of sickness. The treatment of disease is a more expensive process today than it was twenty years ago. It is paradoxical that the enormous contributions which specialties such as radiology have made to modern medicine have increased the cost of sickness by multiplying the valuable aids which

medical men have at their disposal for improved methods of diagnosis and therapy. I am inclined to agree with Dr. Kirklin in urging that radiologists seriously deliberate the possibilities of reducing the cost of x-ray diagnosis by any means that is consistent with service of high quality. There is good reason to believe that the income of radiologists would be increased rather than decreased if the cost of roentgen consultation were reduced.

If the cost of x-ray examinations could be decreased, a more recent threat confronting this specialty would likely be removed. During the past several years there have been frequent proposals, both by laymen and medical men, for tax-supported "diagnostic centers" to which clinicians could refer patients for a free or low-cost "work-up." I wonder how many radiologists are aware that the president of the American Medical Association, in his inaugural address last year, advocated state diagnostic centers to provide x-ray and laboratory service? One state medical society has very recently adopted resolutions requesting the state public health department to provide free diagnostic services for patients, regardless of their financial status. Personally, I am not seriously alarmed by the imminence of this threat to the private practice of radiology, but it is a development that should be neither minimized nor ignored.

Whatever policies the specialty of radiology adopts, and whatever methods it pursues in efforts to preserve the standards it has erected for its disciples, it is imperative that radiologists resolve their differences of opinion and devote their full energies to the advancement of the principles of good radiologic practice. One thing must be recognized as essential: practitioners of radiology must maintain a unified front through active local societies and a strong national body that can project their concepts in the deliberations of national agencies that will help to shape the order of things to come.

Thus armed, they can face the future with the confidence and fortitude urged by Sir William Osler when he advised physicians to meet their common problems "with the reinforcement born of hope, or the strong resolution of despair."

---

\* EDITORIAL COMMENT: The Workmen's Compensation Fee Schedule of New York State represents a 20 per cent reduction on normal or usual fees for diagnostic radiology. This schedule was accepted by radiologists of New York because it represents a net or "no collection loss" basis of remuneration. This is the presently applied schedule in use by the nonprofit medical expense insurance companies of New York State.—*Alfred L. L. Bell, Chairman, Section on Radiology.*

#### GRANT FOR MENTAL HYGIENE

The Commonwealth Fund has given \$10,000 to the National Committee for Mental Hygiene to provide fellowships to train psychiatrists for work with children. Both basic training and advanced study as well as refresher courses will be provided by the fellowships.

#### LIBRARY ACQUIRES RARE VOLUME

Acquisition of a copy of the 1555 edition of *Fabrica de Humani Corporis* by Andreas Vesalius, one of the oldest existent textbooks on anatomy, for \$700 has been announced by the State Medical Library. Maud Nesbitt, librarian, said the wood-bound volume would be stored in a vault.

# PLATYBASIA AND OCCIPITAL VERTEBRA CAUSING FORAMEN MAGNUM ENCROACHMENT AND RESULTING NEUROLOGIC SYMPTOMS

LEE A. HADLEY, M.D., Syracuse

**C**ONSTRICTION of the foramen magnum by certain congenital conditions has been shown to produce progressive neurologic symptoms simulating, among others, multiple sclerosis, syringomyelia, and progressive spastic paralysis. Since these congenital abnormalities of the upper cervical region are amenable to surgery, careful radiographic studies should be undertaken of all patients supposed to be suffering from one of these hopeless neurologic conditions.

The skull base is said to originate from a fusion of at least three embryologic cervical segments or scleromeres. Any level of the spine may at times congenitally assume the characteristics of that level immediately above or below it, so that a complete or partial atlanto-occipital fusion may take place. More rarely one sees the opposite tendency, that is, for the lowermost segment of the base of the skull to assume the vertebral form, the so called occipital vertebra. In both of these conditions a constriction of the foramen magnum is likely to be present.

With atlanto-occipital fusion the neural arch of the atlas may or may not be complete posteriorly. It may be fused to the occiput in one or both sides. Flexion-extension studies will show that it does not separate from the base of the skull upon extreme forward flexion. Fusion of two or more cervical segments is likely to be present. Displacement of the odontoid process upward into the foramen magnum decreases the A-P diameter of this opening and its shape may become distorted. The resultant flattening of the bialar area is spoken of as a congenital platybasia.

The required type of platybasia is secondary to softening of the base of the skull as in Paget's Disease, osteomalacia, or hyperparathyroidism. The skull base is invaginated by the cervical spine like a thumb pressing against a soft rubber ball, thrusting it upward into the posterior fossa. With this bialar impression the occiput is convex upward, showing as a reverse curve. The foramen magnum may be as high as the petrous pyramids and funnel shaped, but not necessarily distorted in outline. The base does not fuse with the occiput, and flexion-extension studies show a movement between the skull and the atlas. Operation is probably not indicated in the acquired type.

Common to both types is the high position of the first cervical segment above the line from

the hard palate to the posterior margin of the foramen magnum described by Chamberlain. The petrous pyramids are raised above their normal position and distorted in shape. The clivus is nearly on a plane with the floor of the anterior fossa. The neck is short, with lessened movement of the head, which may be carried at an angle. There is likely to be exaggeration of normal anterior cervical curve, in which case the foramina will be smaller than usual.

Elevation of the base of the skull, like a piston, into the posterior fossa, limited above by the firm tentorium, may produce compression by the cerebellum and force a part of its substance to herniate downward into the cervical canal, simulating the so called Arnold Chiari malformation. There is likely to be compression of the cord of cranial nerves.

## Occipital Vertebra

This condition results from incomplete assimilation of the most posterior of the three scleromeres which form the base of the skull. That is, the area about the foramen magnum assumes certain features resembling a vertebral segment. (1) There is a hypochordal arch, partially or completely fused to the anterior margin of the foramen magnum, and (2) a partial or complete neural arch outlined about the dorsal surface of the foramen. (3) Transverse processes may or may not be present—more or less fused to the base of the skull. If present they do not bear a foramen for the vertebral artery. (4) These masses, bearing the condyles, may or may not encroach upon the foramen, distorting its shape. (5) The condyles resemble those of the normal subject. (6) The so called third condyle, *ossiculum terminale*, may be present in the anterior portion of the foramen. This is a separate ossicle developed from the notochord in the terminal ligament of the odontoid and may embryologically in the normal subject form the tip of this structure. Analogous to the relationship between the atlas and the dens, the third condyle corresponds to the body of the occipital vertebra with the hypochordal arch in front and the neural arch behind.

## A Case of Occipital Vertebra

An 11-year old girl studied by the author showed the following neurologic symptoms:

Although the temperature and tactile perception were normal on the right side of the body, on the

FIG. 1. Diagram illustrating the three stages of embryologic development. Three of the original somites are incorporated into the base of the skull. The atlas originates from  $1\frac{1}{2}$  segments, while each vertebra below that is said to arise from a caudal and cephalic half of two adjacent somites. The intervertebral artery separates the different somites and later supplies the vertebral bodies, while the intrasomatic cleft marks the point where the intervertebral disk eventually develops. Since the nerves develop from the more densely staining anterior portion of the somite, each vertebral segment has one pair, except the first cervical, which has two pairs. The odontoid process of the axis actually originates as the vertebral body of the first segment but later fuses with the second. At times the posterior atlanto-occipital ligament ossifies, forming the ponticulus posterius arching over the foramen arcuale, which transmits the vertebral artery and suboccipital nerve. This bony arch is said to arise from the extra half somite of the first cervical segment and corresponds to the pro-atlas of certain vertebrates. The ossiculum terminale develops from the lowermost segment of the occiput in the terminal ligament of the odontoid. It may even be fused with and form the tip of that structure. The so-called occipital vertebra, if present, is seen as a tendency for the lowermost occipital segment to assume certain features of a cervical vertebra surrounding the foramen magnum.

1. Foramen Magnum.
2. Ossiculum Terminale
3. Odontoid Process.

FIG. 2. Case of occipital vertebra. Diagram to illustrate relations of (1) saddle-shaped foramen magnum, (2) ossiculum terminale (third condyle), and (3) shortened odontoid process.

left side there was hypo-esthesia to tactile and pain stimuli and heat perception was lost, while cold was interpreted as a painful sensation of heat. Tendon reflexes were exaggerated on the right side and normal on the left. Abdominal reflexes were present on the right and absent on the left. There was a strong Babinski and some disturbance of coordination.

In this case the radiographs showed:

1. A normal atlas.
2. A broad, short odontoid process.
3. The posterior margin of the foramen magnum was thinned and below normal level. At operation this was found to bear, somewhat laterally, two cornua—indicating the rudimentary, incomplete neural arch.
4. The outline of the foramen magnum was shaped like a bicycle seat. This was caused by two

bony masses projecting from the sides of the foramen and encroaching upon its anterior portion.

5. The ossiculum terminale appeared within this narrowed portion as a distinct oval-shaped ossicle entirely separate from the odontoid.

Laminectomy of the first and second arches and enlargement of the foramen magnum were done by Dr. Ward Williams. This revealed a circular fibrous constriction of the dura at the level of the foramen. As this was dissected away in layers there was a progressive expansion of the dural sheath to its normal diameter.

Recovery was uneventful and two months later the child returned to school. Six months past operation, the Babinski was no longer present, but the other neurologic signs had remained unchanged. It is probable, however, that the progressive development of further neurologic symptoms has been prevented.

Fourteen months after operation, re-examination of this child revealed the neurologic findings to be essentially unchanged.

FIG. 3. Case of occipital vertebra. Foramen magnum shaped like a bicycle seat, narrowed in front by masses projecting into its lumen from each side.

FIG. 4. Ossiculum terminale (retouched) partially overlying the shortened odontoid.

### Conclusion

Foramen magnum distortion with confusing neurologic symptoms may be caused by atlanto-

occipital fusion (basilar impression, platybasia) or by an occipital vertebra. These latter conditions can only be diagnosed by careful radiographic studies.

### OFFICE OF VOCATIONAL REHABILITATION

The appointments of Dr. Victor H. Vogel, Surgeon, U.S. Public Health Service, as consultant in psychiatry, and Dr. Mark E. Gann, Surgeon (R), U.S. Army, as representative of the Federal Bureau of Investigation, Office of Vocational Rehabilitation, to the Office of Vocational Rehabilitation, U.S. Public Health Service, will include the organization of programs for the rehabilitation of persons with psychiatric disabilities, and mental hygiene programs for all handicapped persons who are clients of State rehabilitation agencies. The Federal-State grant-in-aid program for the voca-

### APPOINTS TWO PHYSICIANS

pital, 1937-1938, and at the Johns Hopkins Medical School, 1939-1940. He is a diplomate of the National Board of Neurology and Psychiatry and a Fellow of the American Psychiatric Association. Dr. Vogel served as assistant chief, Mental Hygiene Division, and mental hygiene consultant to the States, U.S. Public Health Service, 1940-1942.

Dr. Gann has been assigned to the Office of Vocational Rehabilitation to assist in the inauguration of the interpretation of the vocational re-

western area. Dr. Gann is a graduate of the Johns Hopkins School of Medicine, 1933. He received training in surgery at the Sinai Hospital, Baltimore, Maryland, 1933-1938, and engaged in the private practice of general surgery in Baltimore from 1938 to 1943.

Prior to his assignment to the Office of Vocational Rehabilitation, Dr. Gann's field of active duty with the U.S. Public Health Service included industrial surgery and participation in the medical care project in the Mobile, Alabama, War Housing Clinics.

FIG. 1. Diagram illustrating the three stages of embryologic development. Three of the original somites are incorporated into the base of the skull. The atlas originates from  $1\frac{1}{2}$  segments, while each vertebra below that is said to arise from a caudal and cephalic half of two adjacent somites. The intervertebral artery separates the different somites and later supplies the vertebral bodies, while the intrasomatic cleft marks the point where the intervertebral disk eventually develops. Since the nerves develop from the more densely staining anterior portion of the somite, each vertebral segment has one pair, except the first cervical, which has two pairs. The odontoid process of the axis actually originates as the vertebral body of the first segment but later fuses with the second. At times the posterior atlanto-occipital ligament ossifies, forming the ponticulus posterior arching over the foramen arcuale, which transmits the vertebral artery and suboccipital nerve. This bony arch is said to arise from the extra half somite of the first cervical segment and corresponds to the pro-atlas of certain vertebrates. The ossiculum terminale develops from the lowermost segment of the occiput in the terminal ligament of the odontoid. It may even be fused with and form the tip of that structure. The so-called occipital vertebra, if present, is seen as a tendency for the lowermost occipital segment to assume certain features of a cervical vertebra surrounding the foramen magnum.

1. Foramen Magnum.
2. Ossiculum Terminale
3. Odontoid Process.

FIG. 2. Case of occipital vertebra. Diagram to illustrate relations of (1) saddle-shaped foramen magnum, (2) ossiculum terminale (third condyle), and (3) shortened odontoid process.

left side there was hypo-esthesia to tactile and pain stimuli and heat perception was lost, while cold was interpreted as a painful sensation of heat. Tendon reflexes were exaggerated on the right side and normal on the left. Abdominal reflexes were present on the right and absent on the left. There was a strong Babinski and some disturbance of coordination.

In this case the radiographs showed:

1. A normal atlas.
2. A broad, short odontoid process.
3. The posterior margin of the foramen magnum was thinned and below normal level. At operation this was found to bear, somewhat laterally, two cornua—indicating the rudimentary, incomplete neural arch.
4. The outline of the foramen magnum was shaped like a bicycle seat. This was caused by two

bony masses projecting from the sides of the foramen and encroaching upon its anterior portion.

5. The ossiculum terminale appeared within this narrowed portion as a distinct oval-shaped ossicle entirely separate from the odontoid.

Laminectomy of the first and second arches and enlargement of the foramen magnum were done by Dr. Ward Williams. This revealed a circular fibrous constriction of the dura at the level of the foramen. As this was dissected away in layers there was a progressive expansion of the dural sheath to its normal diameter.

Recovery was uneventful and two months later the child returned to school. Six months past operation, the Babinski was no longer present, but the other neurologic signs had remained unchanged. It is probable, however, that the progressive development of further neurologic symptoms has been prevented.

Fourteen months after operation, re-examination of this child revealed the neurologic findings to be essentially unchanged.

Microscopic examination of the specimen showed that the lesion was cystic. The lumen was partly filled with debris. The inner wall was lined with stratified squamous epithelium. At one area this wall was replaced by a mass of granulation tissue.

#### Diagnosis epithelial cyst

The relationship of trauma to the production of epithelial cysts is accepted by many. King<sup>1</sup> reported 19 cases with a definite history of trauma in 12 cases. Wien and Caro<sup>3</sup> reported three cases with a definite history of trauma in 1 case and suggestive in 2. Buerger<sup>9</sup> reported 2 cases of epithelial cysts on the fingers following puncture wound with a needle. Boggs and Goodale<sup>4</sup> reported 2 cases, one of which followed puncture wound with a wooden sliver. Yiehmin and Summerill<sup>10</sup> report a case of epithelial cyst in the terminal phalanx of the right fourth finger following injury. Love and Montgomery<sup>8</sup> found only two cases of traumatic epithelial cysts in their series of 271 cases of epithelial and sebaceous cysts. In our group of cases there was a definite history of trauma with piercing objects in 2 cases.

While all writers on the subject admit that trauma plays a part in the production of these cysts, yet the method by which this is produced as well as the source of the epithelium is still controversial. Franke<sup>11</sup> was of the opinion that these cysts arise from stimulated embryonic cell rests and that trauma was the stimulus. Wien and Caro<sup>3</sup> and Reverdin<sup>12</sup> are of the belief that in the course of an injury bits of epidermis are implanted into the corium. The cyst then arises from this implantation. This view was supported by the experimental work of Kaufmann,<sup>13</sup> Scheveninger<sup>14</sup> and Davis and Traut<sup>15</sup>. These investigators were able to produce cysts in lower animals following implantation of epidermis. Peer,<sup>16</sup> and Peer and Paddock<sup>17</sup> on the other hand in their work on the fate of buried skin grafts in man were unable to show cyst formation. They were not of the belief that implanted epidermis following injury could produce epithelial cysts. Broders and Wilson<sup>6</sup> suggested that these cysts arise from the ducts of sebaceous cysts. Pels Ieusden<sup>18</sup> suggested that cystic lesions could be produced around foreign bodies. He suggested that a break in the skin was necessary for implantation of epithelium.

Epithelial cysts occurring on the palms can be easily mistaken for similar appearing lesions. The lesions which are commonly confused with epithelial cysts are ganglia, fibromata and sebaceous cysts. Ganglia occur on the dorsal surface

of the hand. They are larger and connected with a tendon sheath and contain a thick viscous fluid. Fibromata are solid tumors composed of fibrous tissue. Sebaceous cysts have a definite histologic picture and do not occur on the palms.

For the treatment of epithelial cysts all writers agree that complete surgical removal is the method of choice.

#### Discussion

In our group there was a definite history of trauma from piercing objects in 2 cases. In one of these cases there was a history suggestive of a foreign body. None was found on careful examination of the specimen after removal. His histologic examination of both of these specimens showed that one section of the wall of the cyst was replaced by granulation tissue containing giant cells of the foreign body type. This area, we believe, is the site of puncture with the object producing the break in the epithelium.

It is our belief that these cases support the theory of implantation of epithelium following injury. In the remaining cases the patients were engaged in occupations that required the constant use of their hands. Whether injury without any demonstrable break in the skin can produce such lesions is not clear. It is, however, possible that in the course of their work the patients may have suffered some trivial injury to the parts which could initiate these tumors.

#### Summary

Four cases of epithelial cysts of the palms are reported with a review of the pertinent literature.

# SURVEY OF 116 CASES OF PNEUMONIA IN A HOSPITAL SERIES AND 22 CASES OF PNEUMONIA IN A COLLEGE INFIRMARY SERIES

## X-Ray Findings in Connection with Chemotherapy

CHESTER O. DAVISON, M.D., Poughkeepsie, New York

THERE seems to be a general impression that the sulfonamides clear up pneumonia clinically but leave considerable residue evident on x-ray films. An exhausting but not exhaustive search of the literature does not seem to bear this out. Some clinicians state that there seem to be more residual physical signs after clinical improvement than in "presulf" days.

Titelbaum<sup>1</sup> reports a series of several cases checked from thirty to seventy-seven days after the onset of resolution before a normal appearance on the roentgenogram could be noted.

A medical officer in one of the large Army camps stated "unofficially" that in virus pneumonia or primary atypical pneumonia it was observed that there was a very direct relation to the sedimentation rate and x-ray-demonstrable improvement. A clear film was to be expected following a drop in the sedimentation rate.

Recently Showacre, Wightman, and Moore,<sup>2</sup> in two articles on primary atypical pneumonia recording a careful study done at Cornell University, Ithaca, state in the second article: "Clinical improvement has been noted in the face of an apparent x-ray spread."

As applying to pneumococcus pneumonia, in response to a personal inquiry, Dr. William Tillet<sup>3</sup> of the New York University College of Medicine made this statement: "If pneumococcus pneumonia is not complicated by pleural effusion or factors which delay resolution or if the pneumonic infection is not superimposed upon some other pre-existing pulmonary disorder, it is my personal opinion that there is no lag in the x-ray clearing of pulmonary infections following chemotherapy."

In trying to find out something firsthand about the subject, we asked our record clerk at Vassar Brothers Hospital, Poughkeepsie, for 200 consecutive charts with a final diagnosis of pneumonia. Practically all of these patients had had some type of sulfonamide administered, and in a fairly regular pattern of dosage. "Virus pneumonia" appeared as a diagnosis only eight times. There were 51 typed pneumococcus pneumonias.

Eighty-two charts were excluded because they were incomplete, lacking such information as an x-ray or a white blood count and some because

the patient was admitted *in extremis*. We also reviewed 22 consecutive cases from Vassar College Infirmary which had been diagnosed as pneumonia, making a total of 140 included in this survey. These were divided into seven groups as follows (Chart 1):

Group T: All those with a positively typed pneumococcus.

Group A: No positive pneumococcus-type sputum. Temperature above 103 F.; white blood count level above 10,000; hospital stay twelve days or less. These factors were chosen arbitrarily after looking over a number of pneumonia charts.

Group A-1: Factors the same as in Group A but with a hospital stay of more than twelve days.

Group Q: Temperature 103 F. or more; white blood count level less than 10,000.

Group W: Temperature less than 103 F.; white blood count level greater than 10,000.

Group X: Temperature less than 103 F.; white blood count level less than 10,000.

Group V: This group consisted of the 22 consecutive cases diagnosed as pneumonia by Dr. Baldwin and her associates at the Vassar College Infirmary, extending from 1942 into 1944. All of these seemed to fall into the primary atypical pneumonia group. All of the patients had definite x-ray findings, low fever, low white blood cell count, comparatively long hospitalization, and all had some sulfonamide therapy.

## Hospital Stay as Affected by Sulfonamides

Discharge at twelve days would seem to be a good goal for the uncomplicated pneumonia treated by chemotherapy. The primary atypical pneumonias are reported to require longer convalescence than those due to the pneumococcus or other bacterial agents. In the infirmary group noted above the average stay was twenty-two days. However, in the Cornell group of 196 cases of primary atypical pneumonia it was only twelve days. A report from one Army camp of 382 pneumonias in a six-month period, in which primary atypical pneumonia was the diagnosis in 346 cases, the hospital stay was said to be over twelve days for more than half of the patients, and almost a third were hospitalized over twenty days.

In a series of 1,469 cases of pneumococcus

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

From the Vassar Brothers Hospital, Poughkeepsie, New York

CHART 1

Group	Number of Patients	Temperature	W B C	Average Hospital Days
T	34	103 1 average	13 000 average	15
A	29	103+	10 000+	9
A 1	16	103+	10 000+	18
Q	19	103+	10 000-	14
W	9	103-	10 000+	15
V	9	103-	10 000-	11
Total—all groups	140	101 8 average	7 900 average	22

pneumonia reported by Moore *et al.*,<sup>4</sup> most of them before chemotherapy was in use, the average hospital stay in uncomplicated cases was about fifteen days (14.8). Those with complications stayed an additional twenty-four days. Incidentally, they calculated \$127 per patient as the average additional cost, in hospital expense alone, for complications.

Comparing the small series of Dutchess County sulfonamide-treated cases of pneumococcus pneumonia with the large series of West Coast prechemotherapy cases, the hospital stay does not seem to be strikingly influenced by chemotherapy.

### Response to Drug (Sulfathiazole and Sulfadiazine)

In the hospital series the temperature curve, hospital stay, x-ray findings, discharge notes, etc., were studied in order to get an impression as to the response to the drug. As estimated by a roentgenologist in a swivel chair, the clinical response was good in 65 per cent of the patients and fair in about 30 per cent. Complications occurred in fewer than 10 patients, 2 patients died.

In reviewing and correlating the clinical and x-ray findings of the 116 cases with the hospital staff, it was noted that there was a temperature boost shortly after administering the drug in 35

per cent of 100 cases, followed by good response. It was pointed out by some of the staff that the variation in morning and afternoon temperature and other factors must be taken into consideration and that the boost should probably not be attributed to the drug.

### Complications

Two patients had serum, both with complications. One developed serum sickness and remained in the hospital seventy-seven days. The exact number with pleurisy is indefinite, but 2 had residual changes due to pleurisy. Complete suppression of the function of one kidney, caused by blockage of a ureter by sulfonamide crystals, was demonstrated in one patient.

### Resumé

X-ray films and charts of 138 pneumonia cases, including patients in all decades up to the ninth and all having had sulfonamide therapy, were reviewed.

Follow-up has been incomplete and no comparison has been made with a prechemotherapy series in the same institution, but the impression is that (1) there has been no noticeable speeding up of resolution and (2) there is no definite justification, as yet, for believing that the residual changes observed in this series are caused by the drug used rather than by other factors, such as the type of infection and the state of health of the particular lung parenchyma involved.

### DR. WOLBERG CONDUCTING SEMINAR ON HYPNOSIS

The Association for the Advancement of Psychotherapy has announced that a seminar on "Hypnosis as an Adjunct to Psychotherapy" by Dr. Lewis R. Wolberg will be presented for ten Thursday evenings in the studio at 112 East 55th Street at 8:45 P.M.

The seminar began on October 5

and as instructor in psychiatry at the New York Medical College Flower and Fifth Avenue Hospital,

will cover a wide field of topics, including "Historical Aspects," "Phenomena of Hypnosis," "Suggestion," "Regression," "Crystal Gazing," "Play Therapy," "Dramatization," "Dream Induction," "Suggestion," "Persuasion," "The Manipulation of the Hypnotic Transference," "Detailed Hypnotic Treatment of a Case of Schizophrenia," "Detailed Hypnotic Treatment of Psychoneurosis," and miscellaneous cases.

# Therapeutics

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the December 1 issue and will concern "Evaluation of Local Antisepsis."

### Management of Abdominal Distention

DR. C. H. WHEELER: The subject of our discussion today is the management of various types of abdominal distention. We mean to say something not only about paralytic ileus and other more severe forms of abdominal distention but also about the sort of abdominal distention which occurs as a medical problem in diseases such as typhoid fever and pneumonia.

Dr. Andrus is going to open the discussion.

DR. WILLIAM DEW. ANDRUS: Abdominal distention is a distressing accompaniment of many medical conditions and in the various degrees, from "gas pains" to extreme paralytic ileus, it requires constant attention in surgery. I shall discuss briefly the more recent concepts of the origin of this condition, since they have a distinct bearing on the therapy, and then go on to the prevention and treatment, from the standpoint of both the reinforcement of the normal mechanisms and the use of artificial means of relief.

In contrast to earlier conceptions of the origin of the distending gases from putrefaction in the bowel or, later, diffusion from the blood stream, recent experimental work and actual analysis of intestinal gases give strong support to the idea that by far the greater part, variously estimated at from 65 to 90 per cent, actually consists of swallowed air. This is indicated by the fact that the nitrogen content of gas from distended intestinal loops is so nearly that of air—70 to 80 per cent—while the same fact eliminates the blood stream as the source of nitrogen at least. As the distention increases to the point of venous stasis in the vessels of the mesentery, carbon dioxide passes into the lumen and comes to represent about 10 per cent of the retained gas. The remainder is made up largely of oxygen, hydrogen, and methane.

These facts, while not necessarily contra-indicating some of the older therapeutic methods, do serve to indicate why they are sometimes ineffectual and to point the way toward a more rational plan of prevention and treatment.

In surgical cases the mildest form of disten-

tion appears as the "gas pains" so often seen from two to five days after an abdominal operation. These can be greatly minimized by four measures: (1) operating on a nearly empty intestinal tract; (2) limiting the handling of the bowel to a minimum; (3) limiting the use of morphine and atropine; and (4) the use of enemata with or without smooth-muscle-contracting drugs such as pitressin or prostigmine. The milder cases often yield to a heat pad on the abdomen and a rectal tube.

One should interject at this point the observation that certain of the therapeutic measures collide with the more modern conceptions of pre- and postoperative care of cases requiring intestinal surgery and are therefore to be used with caution or at least with the understanding that some of their effects may require correction.

A wide variety of enemata are used, among which the soapsuds enema with a small amount of turpentine, the water and glycerine enema with or without magnesium sulfate, and the milk and molasses enema are perhaps the best known. Usually "gas pains" are merely annoying, but if they persist they should suggest the possibility of a more serious complication.

True ileus may, of course, be of two varieties—the true mechanical type with cramp-like pain, vomiting which is copious and often forceful, and audible borborygmi, and the paralytic, with pain not a marked feature and, if present, tending to be constant, vomiting of small quantities at frequent intervals, "overflow vomiting," and no audible borborygmi.

Paralytic ileus may occur in localized form, one of the most common of which is dilatation of the stomach. This condition makes its appearance often as hiccups which disappear promptly as the intragastric pressure is reduced. In its acute form dilatation of the stomach may be very serious and rapidly progressing, with severe circulatory symptoms supervening as the elevation of the diaphragm increases. Recognition of the condition is an immediate indication for passing a stomach tube, and this commonly

relieves the patient at once. This is one of the situations in which it is best to leave in a small-caliber stomach tube for several days to prevent recurrence.

Before operations on the stomach or upper intestinal tract it has become almost routine to pass such a tube, and after operation to apply mild suction as a means of preventing both the passage of swallowed air into the bowel and the accumulation of regurgitated intestinal content in the stomach. Indeed, as is so well demonstrated in the so-called Wangenstein suction, it is possible to decompress the upper intestine quite satisfactorily by this method. The amount of fluid drainage obtained represents the normally reabsorbed secretions of the stomach and sometimes of the upper intestine, a vital supply of base and chloride which must be replaced. To this end it is necessary to keep track of the amount of drainage obtained and to follow the blood chemistry. This represents perhaps the modern counterpart of the dehydration and demineralization which may be precipitated by the persistent use of drastic catharsis in both the pre- and post-operative care of surgical cases. True, getting the patient's bowels to move at a reasonable time after operation is important for his comfort, but for this violent catharsis is almost never required and in any event should not be repeated often. When one realizes the extent to which the most violent catharsis used to be used in surgery, some of the poor results seem more easily explained.

In the treatment of paralytic ileus coming on after other types of operation, such measures as heat applied to the abdomen, enemata, and, if indicated, oxytocic medication are usually employed before resorting to suction drainage of the stomach. These means of reinforcement of the natural processes usually accomplish the desired result, but in any patient with hiccups or vomiting the stomach tube is indicated and often relieves the complication in a spectacular fashion. The Miller-Abbott tube has proved a great boon in the handling of paralytic ileus and has practically displaced enterostomy in this condition. Getting it to pass into the duodenum may be troublesome at times, but this can usually be accomplished and the effects as the tube passes along into the bowel are most gratifying.

I mentioned earlier the signs differentiating paralytic from mechanical ileus because of the fact that certain measures, notably the employment of smooth-muscle-stimulating drugs, may be contraindicated in the latter. Indeed, it may be said that except in the later stages of mechanical ileus, when hyperactivity of the bowel above is replaced by atony, the body is providing all the propulsive force needed, and when atony super-

venes it is evident that the obstruction is complete. Even in early cases of mechanical ileus resort to intragastric suction is indicated and this may obviate the necessity of further measures in some cases. In persistent mechanical ileus, however, the only cure is release of the obstruction.

When patients with ileus are first seen a certain routine is advisable, including the passage of a small tube into the stomach, the giving of an enema, and, if not otherwise contraindicated, the starting of an infusion after taking blood for determinations of chlorides, nonprotein nitrogen, and carbon dioxide combining power. These measures establish a base-line against which further changes in the patient's condition can be gaged.

Perhaps the most stubborn cases of paralytic ileus encountered in surgery are those associated with retroperitoneal hemorrhage from fractures of the vertebrae or wounds. These may be very stubborn and require constant vigilance for control. Pitressin, prostigmine, and intubation may all be required.

In conclusion, let me stress the fact that the prevention of distention is most important and can be accomplished at times only by resorting to the passage of a small stomach tube and applying mild suction. More and more evidence is accumulating indicating that the source of much of the distending gas is swallowed air. Maintenance of adequate tone of the musculature of the bowel is also of importance.

DR WHEELER: I think that from the standpoint of medical diseases there is very little to add to what Dr. Andrus has said. The medical doctor encounters the abdominal distentions as a problem most frequently in the severe infections such as typhoid fever, pneumonia, and septicemia. As Dr. Andrus has pointed out, in medicine as in surgery it is usually easier to keep a patient with pneumonia or typhoid fever from getting distention than it is to reduce his distention after it has occurred. This, I think, is best accomplished with the use of frequent enemata and laxatives. There are numbers of remedies which are included in all descriptions of the treatment of abdominal distention in medical cases, such as the turpentine stupe and heat applied to the abdomen. Other practitioners apply ice bags to the abdomen, or give enemata with turpentine, etc., which are supposed to stimulate the colon to contract rather than merely to empty it, and use diets which are low in carbohydrates, or low in other things. It is my impression that none of these measures is particularly useful in a patient with typhoid fever who is markedly distended. It seems to me that the enema, the rectal tube, and a few

drugs, such as pitressin, usually given in a dose of 1 cc. hypodermically, or prostigmine methyl-sulfate in a dose of 0.5 mg., are the most effective measures. I should like to ask Dr. Gold what he thinks about the choice between pitressin and prostigmine in the management of abdominal distention.

In pneumonia we see beneficial results in abdominal distention from the administration of oxygen. It seems, frequently, that the tympanites which these patients develop may be related to anoxemia and the use of oxygen helps them.

I should like to ask Dr. Andrus whether he thinks the use of the Miller-Abbott tube or the Wangenstein suction is useful in cases of pneumonia and typhoid fever. To the best of my knowledge these technics are practically never used on the medical wards and I wonder if we are failing to use something which might be helpful.

DR. ANDRUS: I think one has to decide whether the discomfort, or even the hazard, so far as aspiration is concerned, of the continued presence of a small tube passed down through the nose and pharynx into the esophagus outweighs the possible comfort to the patient in the relief of some, at least, of his respiratory distress by the decompression of the upper portion of the intestinal tract. It is possible that it might be found useful, but I think those are the points which have to be considered.

I am glad that you mentioned the use of oxygen in distention, as I had omitted it from my consideration. In many cases the prolonged inhalation of high oxygen mixtures with the B.-L.B. mask, for example, does have a definitely beneficial effect on abdominal distention. There are certain theoretic considerations as to how it acts, which I don't think we need go into, but suffice it to say that it is a well-recognized method.

Probably the percentages which are obtainable with the ordinary oxygen tent would not be very effective, but with the B.L.B. mask the high concentrations obtainable are useful.

DR. HARRY GOLD: You mentioned the milk-and-molasses enema. Could you tell us how that is supposed to work?

DR. ANDRUS: I think perhaps that is one of the residua of older medical practice. I have no idea how it works but I can attest to the fact that it does work in startling fashion. Sometimes the nurses object to it because it is a bit messy, but it does work.

DR. GOLD: How much is administered?

DR. MORRISON: I think it is 100 cc. each of molasses and milk.

DR. GOLD: Is it fairly prompt in its action—within half an hour or many hours?

DR. ANDRUS: It is usually prompt. Do you have any comments on that?

DR. MORRISON: I have used it only two or three times, not more often chiefly because of the nurses' objections, but it does give very excellent results—I think a little better than the ordinary enemas.

DR. ANDRUS: It is less irritating.

DR. WALTER MODELL: I should like to ask about gas swallowing, either in eating or drinking. How can you tell the patient not to do it?

DR. ANDRUS: Something can be accomplished. When the prone patient is fed he is very apt to swallow air. If he can sit up and eat slowly, as he ordinarily would, he is less apt to swallow air.

DR. McKEEN CATTELL: I was wondering about the reasoning that since the composition of the gas in the intestine is similar to that of expired air it must have its source in swallowed air. It seems to me the constituents might well be in equilibrium with the gases of the blood just as is the case between the alveoli and the blood.

DR. ANDRUS: The nitrogen content of the blood is not so high as it is in the bowel. How can diffusion occur to the extent of 70 per cent of the content of the gas in the bowel from a percentage of circulating nitrogen such as exists in the blood?

DR. CATTELL: My question was based on the theoretic consideration that if the blood plasma is in equilibrium with the alveolar air, that the same relationship should hold between the blood plasma and any other gas in contact with the tissues. Nitrogen is, of course, less soluble than oxygen in the blood plasma, there being approximately twice as much oxygen at a given pressure. However, because of the higher partial pressure of nitrogen, plasma contains from three to four times as much nitrogen as it does oxygen. These considerations have been directly confirmed in several laboratories where it has been shown, for example, that the air released in the tissues following sudden decompression contains approximately 80 per cent nitrogen.

DR. ANDRUS: While the points mentioned by Dr. Cattell may be of significance, it is difficult for me to believe that this mechanism can explain any severe grade of distention for at least two reasons. First, the quantity of gas obtained by tube in some cases would seem to me to be far greater than could be dissolved in the amount of blood flowing through the intestines. More significant, however, is the fact that the mere presence of a patent tube in the stomach may prevent meteorism entirely. True, this is more easily accomplished with mild suction, but if one keeps the stomach empty the bowel beyond

will rarely become distended to any marked degree.

DR. WHEELER: I believe you have not answered the question which I posed with reference to whether there was any logical choice between pitressin and prostigmine?

DR. GOLD: I should say that the choice is more or less arbitrary. There are no criteria for making it. There are situations in which pitressin is effective when prostigmine is not, and vice versa. There is the fact that the mechanism of action of the two is different, one acting directly on the smooth muscle and the other indirectly through a cholinesterase inhibition. One might argue from pharmacologic and perhaps from some clinical evidence that prostigmine is the first choice, although if, after adequate doses, no improvement is obtained, one might then turn to a solution of pituitary or pitressin. By "adequate" I mean doses just short of those causing minor toxic symptoms. Prostigmine is the first choice by reason of the fact that it exerts relatively little action on the coronary circulation, while pituitary solution in large doses causes coronary constriction. This becomes a problem, especially in older people. Posterior pituitary materials in doses effective on the bowel may make patients deathly pale. They look wretched. Has that been your experience?

DR. ANDRUS: We have not used the posterior pituitary preparation as such. Pitressin does cause discomfort in patients and will induce pallor every now and then.

DR. GOLD: Small doses which rarely cause pallor are likely not to be dependable in their action on the bowel. When the dose causes a vigorous effect on the bowel, the patient often does not look well. However, looking pale is not a serious matter.

In the case of prostigmine, one can build up the amount in the body by repeating the dose of 0.5 mg. of the methylsulfate hypodermically every thirty minutes without obtaining much of a change in the appearance of the patient, although the patient may begin to feel pretty wretched. When the doses of prostigmine are large enough, the patient begins to vomit and may develop abdominal cramps, whereas with pituitary solution or pitressin vomiting is rather unusual.

Again, then, my first choice would be prostigmine, repeating the dose until abdominal distention begins to go, or there is some salivation, flushing, or nausea. If, at the point of these minor toxic effects, no appreciable beneficial effect on the bowel has taken place, one turns to pituitary preparations.

DR. WHEELER: How frequently could prostig-

mine be used with a patient who has been distended over a period of days? Is there some cumulative or other effect?

DR. GOLD: Prostigmine is not highly cumulative. The material is rapidly excreted. A good plan is to repeat the dose, at intervals of one-half to one hour, until there are signs of action. Then the interval is prolonged to two or three hours or more to maintain the action. If necessary, it may be continued for days without significant accumulation.

DR. CATTELL: Why do you talk about prostigmine instead of physostigmine? Is there any choice between the two?

DR. GOLD: Prostigmine solutions are more stable and prostigmine is a somewhat more potent compound than physostigmine, so that smaller doses are used in the case of the former. I don't believe that there is any significant qualitative difference between the action of prostigmine and of physostigmine or eserine. One may consider them quite interchangeable. Would you agree?

DR. CATTELL: Yes.

DR. WHEELER: Dr. Deitrick, I should like to ask you if you think the character of the diet is of any importance in the prevention of distention, or in the reduction of severe tympanites after it has occurred—for example, in a patient with lobar pneumonia.

DR. JOHN B. DEITRICK: When I am faced with a patient with abdominal distention, whether the food is digestible or not is the question which concerns me most. Ordinarily we say that these patients should not be given carbohydrate because of fermentation. In my opinion, this factor is rarely a matter of importance.

DR. WHEELER: It is not clear to me what digestion has to do with tympanites.

DR. DEITRICK: Impaired digestion is both a cause and an effect of tympanites. If foodstuffs are not properly digested, bacterial action will bring about distention. The distention in turn interferes with the admixture of intestinal juices with the food and leads to further impairment of digestion.

DR. WHEELER: It is interesting to note that all the authorities on typhoid fever agree that severe distention used to be a much worse problem in the days when the patients were starved or given a liquid diet than it was after the high caloric diet came into vogue.

DR. GOLD: I should like to ask about the use of vegetables. It is my observation that vegetables, especially those of the cabbage family, are particularly prone to cause troublesome distention. Does that agree with your experience?

DR. DEITRICK: I think that is true of foods containing much cellulose.

DR. WHEELER: Why should cellulose be a problem?

DR. DEITRICK: It takes longer to break it down and so there is more opportunity for bacterial action. Our intestines do not behave like those of a cow. A cow can digest cellulose, as do all the ruminants. We may break it down to some extent in the large bowel. Most of the cellulose is not digested and because it forms a coating it prevents the digestion of otherwise digestible material. Bacterial growth in the large bowel may break down cellulose and give rise to gas.

DR. GOLD: I should like to ask Dr. Andrus if he will say something about the use of the sulfa drugs in the control of distention. In abdominal surgery a good deal of use has been made of such drugs as sulfaguanidine and sulfasuxidine.

DR. ANDRUS: I can see reasons why sulfa drugs should reduce bacterial fermentation. The sulfa drugs might exert some effect on the lower bowel, particularly in cases of carcinoma of the rectum.

There is another aspect of the situation which I personally should like to hear discussed from the medical and pharmacologic standpoint, and that is the use of laxatives for the patient who has to be in bed for a considerable period of time.

In the patient with acute ileus we are rather shy of using laxatives. We feel that they are contraindicated except in some cases where the use of a mild laxative such as milk of magnesia in dilute form over a period of time may tend to clear up a situation in which it looks as if obstruction were impending.

DR. CATTELL: In connection with the use of laxatives, the distinction between a loss of physiologic function and mechanical obstruction must be important. What is the condition in acute ileus?

DR. ANDRUS: By paralytic ileus we mean that the *vis a tergo* is lost, but there is no mechanical obstruction of the bowel. In mechanical ileus we mean there is a mechanical obstruction of the bowel and, until the later stages, at least, the *vis a tergo* is not only not lost but is greater than ordinary. Does that clarify it?

DR. CATTELL: The differential diagnosis would be pretty important.

DR. ANDRUS: That is the reason I dwelt on the differential diagnosis of the two. In paralytic ileus we used to feel that the thing to do was to use violent cathartics and leave nothing in the stomach or upper bowel. The Miller-Abbott tube, by decompression, has solved that problem pretty well. I raise the question of the use of cathartics particularly in patients who have had a paralytic ileus and have been de-

compressed by the Miller-Abbott tube. It is a question of maintaining the tone of the bowel while a surgical patient is in bed, sometimes for long periods of time, and there are analogous cases in medicine.

DR. WHEELER: Dr. Gold, will you undertake to answer that question?

DR. GOLD: I hardly know how to start. As I see it, the question you put is whether a laxative should be used to maintain the tone, and which one. I should say, offhand, that the answer to the first would be yes, and the answer to the second that it doesn't matter.

DR. ANDRUS: Well, perhaps one should qualify that a bit. Our feeling is that there are any number of relatively mild laxatives which can be used, but that in surgery in general the feeling is to veer away from the violent laxatives, such as castor oil, for example. I am talking about a patient who for some reason or another has need for a laxative.

DR. GOLD: That would seem to make perfectly good sense, because no matter what the cathartic used, the more violent the stimulation the greater the tendency to subsequent depression of the gut. So mild cathartic action is what is wanted, but I also think the matter of the violence of cathartics is not related so much to the type of cathartic as to the amount, and that one can get almost the same results, both good and bad, that one gets out of castor oil from almost all other cathartics if one gives appropriate doses. It is, for the most part, simply a matter of dosage.

DR. ANDRUS: That is a good point.

DR. GOLD: I am wondering how often the use of a laxative, preoperatively and postoperatively or early in the course of the bed-rest period, contributes to the distention. In treating patients with coronary thrombosis, who lie quietly for a long period of time, we make it the rule to let them remain constipated as long as they can tolerate it, and we find that the patient can endure it longer than the doctor, because even on the fifth or sixth day the patient often still has a perfectly flat abdomen; no distention, and no discomfort. Having overcome the patient's psychologic barrier to the notion of going without a bowel movement for some days, the doctor begins to worry over whether things won't go badly if something isn't done to help move the bowels. However, it often happens that trouble begins after this is done. Rumbling, distention, and other bowel discomforts appear right after the bowels have been made to move.

I wonder whether better results in surgical cases are not in part due to the fact that there is a much

WHAT ARE WE LOOKING FOR?

*In vitamin research* we are continually studying nutritional factors of unknown composition, the absence of which cause deficiency diseases. We're looking for more information on the vitamin B complex, we're seeking more facts relating to the fat soluble vitamins A, D and E; we're searching out new dietary factors of clinical importance . . . we're looking for new sources, syntheses, and symptoms.

RESEARCH IS THE  
OPEN SESAME  
TO PROGRESS

Vitamin research by Parke-Davis has contributed much to the development of this field, from the days of our original standardization work back in 1916 down to the recent isolation of vitamin B<sub>12</sub>.

PARKE, DAVIS & COMPANY  DETROIT 32, MICHIGAN

DR. WHEELER: Why should cellulose be a problem?

DR. DETTRICK: It takes longer to break it down and so there is more opportunity for bacterial action. Our intestines do not behave like those of a cow. A cow can digest cellulose, as do all the ruminants. We may break it down to some extent in the large bowel. Most of the cellulose is not digested and because it forms a coating it prevents the digestion of otherwise digestible material. do not depress the activity of the bowel but rather increase it.

DR. ANDRUS: That is true in dogs, certainly.

DR. GOLD: It is so in the cat too, and there are x-ray studies in humans showing that the emptying time of the stomach is delayed but that once the barium gets past the stomach it seems to pass down the bowel very fast. Thus, the constipating action of morphine may not be due to diminished motility but to the fact that reflexes for defecation are suppressed.

DR. ANDRUS: I think part of the blame which has been heaped on morphine as a producer of postoperative distention has been due to the fact that as a medication preliminary to anesthesia it has been combined with atropine. This may be heterodox as far as Dr. Gold is concerned, since I heard him express his opinion with regard to this point before.

DR. GOLD: I think there is not much doubt that morphine or codeine alone causes constipation. It is a common effect of a cough medicine which contains these drugs. Patients often say the medicine relieved the cough but tied up the bowels, and in constipation the ground-work is laid for distention. While I believe that ordinary doses of atropine have little influence on the bowel, they are effective in counteracting the parasympathetic action of morphine on the bowel. Atropine might contribute to constipation, although I am not clear on how it would do it.

DR. WHEELER: How about some question from the Army or Navy?

STUDENT: I should like to ask Dr. Deitrick whether he thinks it is a good idea to substitute simple carbohydrates, such as glucose, in the diet of patients with typhoid fever, as is done in pancreatic insufficiency.

DR. DEITRICK: I think we usually do in the pneumonia patients. We put them on a liquid diet which is composed mostly of carbohydrates and fruit juices. Then we give them plain broth which does not contain much protein and only a little fat. The carbohydrates which they get are in simple form. They are not given any whole wheat or things of that type.

I should like to ask Dr. McLean about postoperative distention in connection with operations on the eye. Isn't that a pretty serious problem?

DR. McLEAN: It is much less a problem than it was, say, five years ago. For many years it was customary in cataract operations, for example, to put the patients flat on their backs in bed and give them liquids through a tube. They were bothered with mild or moderate distention, or occasionally severe, true paralytic ileus. During the last few years we have revised our sur-

gical technics considerably. We get patients up into chairs, or at least have them sit up and move around in bed. We give them a more liberal diet and distention as a major problem has practically vanished.

DR. DEITRICK: I know those patients were formerly put to bed flat on their backs for a week or ten days and they were not allowed to move an arm or leg.

DR. McLEAN: And they would blow up pretty routinely.

### Summary

DR. GOLD: The subject of abdominal distention was under consideration in the conference today. While there was no attempt to explore it exhaustively, many points of interest have been brought up as they apply particularly to the patient who is ill in bed.

*Both the surgeon and the internist have a stake in the problem of abdominal distention. It complicates the postoperative state and gives rise to difficulties in the medical patient, especially the case of systemic infection.*

There seems to be no doubt of the fact that gastro-intestinal motility is disturbed. It may vary from a case of diminished tone with intestinal unrest causing mild "gas pains," through various intermediary stages to complete paralysis in the form of paralytic or mechanical ileus. An important distinction is drawn between the latter two, for cramp-like pain and audible borborygmi are outstanding only in the mechanical type of ileus, which requires prompt removal of the mechanical obstruction.

There are gaps in our knowledge as to how the condition is brought about and where the gas comes from which distends the bowel. Whether the trigger lies in a disorder of the nervous mechanism, direct action on the musculature, or vascular changes in the gut is not established. Whether the gas comes first and brings about secondary changes in the bowel, or whether the changes in the bowel bring about the accumulation of gas in a vicious cycle also remains to be established. The discussion brought out a sharp difference of view regarding the source of the gas. Speaker One argued, from the composition of the gas, which is very high in nitrogen, and from the amount of the gas, that it is mostly swallowed. Another argued, from the law of partial gas pressures on the sides of permeable membranes, that such composition might be expected even if the gas were not swallowed but passed out of the blood into the bowel.

Factors known to predispose to abdominal distention in surgical cases are operation with the bowel insufficiently emptied and excessive

manipulation of the bowel. The kind of anesthetic may play a role. In medical cases infection promotes distention, not only infection involving the intestinal tract directly as in the case of typhoid, but in systemic infections such as pneumonia in which distention is particularly troublesome.

Diet, drugs, posture, and the enema came in for some discussion concerning their part in producing or controlling abdominal distention. The importance of dietary restrictions to prevent and relieve distention is unquestioned, but there is not the same agreement as to the nature of the restrictions. Feeding seems less likely to give rise to distention than starving. That was the experience in the early studies on typhoid fever. Emphasis is placed on the advantage of readily assimilable food (sugar, juices, broths). Vegetables containing abundant cellulose seem to be objectionable because little or none of the cellulose is digested and breakdown by bacterial action may give rise to more gas. Its irritant effects may also cause distress.

There was the question whether oversolicitude about a daily bowel movement may not do more harm than good. There was one view that patients ill in bed frequently show little abdominal distention or distress if inactivity of the bowel is permitted for several days, and that often gas, rumbling, and distention become troublesome only after the bowels have been stirred to action.

It was urged to withhold measures to activate the bowel for four or five days, provided there was not discomfort. To this there was a contrary opinion.

There was general agreement that vigorous catharsis with castor oil or other agents pre- or postoperatively is a potent cause of abdominal distention. The choice of the cathartic seems to be of less importance than the dose, for a

strong cathartic action, no matter what the agent, produces secondary depression in the motility of the gut, the ground work for abdominal distention. There was the suggestion that the enema disturbs the physiology of the bowel less than cathartics and that it might be preferable to cathartics as a means of preventing as well as relieving abdominal distention.

Morphine promotes constipation and abdominal distention and there was the opinion that atropine, often given with morphine, may contribute to it.

The surgeon combats distention successfully by a tube passed into the stomach, and there has been great progress in relieving distention lower down in the intestine by the use of the Miller-Abbott tube and Wangenstein suction. The suggestion was made that this measure might be more often applied in medical cases.

In the way of drugs to increase the tone of the bowel prostigmine methylsulfate in 0.5 mg. doses hypodermically, repeated every hour or so until minor toxic effects appear, if necessary, seems to be the first choice. If this is not effective, solution of posterior pituitary or pitressin in 1 cc. doses by hypodermic injection may be tried. The difference in their mechanism of action and toxic effects was discussed.

In paralytic ileus it is the practice to employ heat applied to the abdomen, the milk and molasses enema, and pitressin or prostigmine before resorting to suction drainage.

The view was expressed that letting the patient sit up for his meals, if possible, is more likely to prevent distention, on the grounds that it leads to less swallowing of air.

Prevention is paramount in the management of abdominal distention. Early treatment is imperative, since it becomes increasingly difficult to control as the condition advances, and fully developed paralytic ileus often leads to disaster.

#### DIPHTHERIA-TETANUS TOXOID, PRECIPITATED

Within recent years, tetanus toxoid has taken its place with diphtheria toxoid and other effective prophylactic agents. Diphtheria-tetanus toxoid, combining the advantages of both preparations in a volume dose approximating that of either and inducing no more reactions, marks a still further advance.

A limited supply of precipitated diphtheria-tetanus toxoid prepared by the Division of Laboratories and Research is now available on application to the central laboratory. It is expected that this toxoid will be ready for general distribution as soon as the demand for it and the extent to which it will be substituted for precipitated diphtheria toxoid can be determined. The toxoid is dispensed in 2.5 and 10 ml. volumes. Directions for its use and the precautions to be observed are the same as for the

precipitated diphtheria toxoid except that two doses of 1 ml. each, a month apart, are required.

As after diphtheria toxoid, the intracutaneous test (Schick) can be used to determine whether immunity to diphtheria has been acquired. There is no similar test for tetanus; hence, in order to maintain an adequate level of immunity against tetanus, a stimulating dose of precipitated diphtheria-tetanus toxoid or of tetanus toxoid alone should be administered at the end of a year. A stimulating dose of tetanus toxoid at the time of any injury for which ordinarily a prophylactic injection of antitoxin would be given, is considered to be sufficient to protect against tetanus infection. *In case of any doubt as to previous active immunization with tetanus toxoid, a prophylactic dose of tetanus antitoxin should be administered.*—*Health News, Sept. 11, 1944*

## Procaine Hydrochloride and Epinephrine

The combination of the prompt and powerful local anesthetic action of procaine hydrochloride with epinephrine is very effective. With CHEPLIN'S PROCaine HYDROCHLORIDE and

EPINEPHRINE the period of anesthesia is prolonged through retarded absorption of the anesthetic. It also causes blanching of the operative area, thus giving the surgeon a clear field.

Literature on request.

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Baehr, M.D., and Charles D. Post, M.D.*

## Transmission of Disease

THE medical staff of Memorial Hospital of Greene County and the Greene County Medical Society met on October 26 at 9:00 p.m. at Memorial Hospital of Greene County, Catskill, for postgraduate instruction.

The lecture was "Transmission of Disease by Lice, Fleas, Ticks, and Other Insects." Dr. Morton C.

Kahn, Ph.D., associate professor of public health and preventive medicine, of the department of public health and preventive medicine of Cornell University Medical College, New York City, was the speaker.

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

## General Medicine

INSTRUCTION in general medicine was given to the Madison County Medical Society on October 26 at 8:00 p.m. at the Hotel Oneida in Oneida.

The first lecture was "Traumatic Surgery with Emphasis on the Treatment of Wounds and Shock," by Dr. Emmett A. Dooley, assistant clinical professor of surgery at New York Post-Graduate Medical School, Columbia University.

This was followed by "The Therapy of Thyroid Disorders, Including Thiouracil," given by Dr. Ivan Hekimian, assistant professor of medicine at the University of Buffalo School of Medicine, Buffalo, New York.

The first lecture was provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health.

## Instruction in Obstetrics

INSTRUCTION in obstetrics was given by Dr. Harvey B. Matthews, clinical professor of obstetrics and gynecology, Long Island College of Medicine, Brooklyn, when he spoke on "Forceps Delivery—Indications, Dangers, and Accomplishment" at a meeting of the Saranac Lake Medical Society held

October 11 at 8:00 p.m. in the John Black Room, Saranac Laboratory, Saranac Lake, under the auspices of the Council Committee on Public Health and Education of the Medical Society of the State of New York in cooperation with the New York State Department of Health.

## SIXTH WAR LOAN DRIVE STARTS NOVEMBER 20

All company War Bond chairmen for the Sixth War Loan will be officially designated as members of the War Finance Committee for New York under a new plan adopted by the committee's Payroll Savings Division.

The plan, providing a close link between company bond leaders and the War Finance Committee, is expected to facilitate the internal promotion of the War Loan drive in each company and in turn to stimulate a greater sale of extra bonds during the drive, scheduled to begin November 20.

The presidents of more than 10,000 business organizations in New York City already have begun the selection of their company chairmen, according to Frank B. Mitchell, senior deputy manager of the Payroll Savings Division, who is supervising the program.

When all of the appointments are completed, the enrolled Treasury Representatives will receive identification as War Finance Committee members.

The new plan is expected to speed up the distribution of Sixth War Loan supplies and material, Mr. Frank Mitchell said, enabling the companies to get off to a flying start in the drive early in November. Since purchases of Series E, F, and G bonds made during November count toward the Sixth War Loan goal, utilization of the plan will permit the company chairmen to start selling bonds and securing pledges before the actual opening day of the drive, on November 20. It will also mean that employees who purchase their extra bonds on the payroll deduction or cash installment basis will be able to spread their payments over a longer period, thus making it easier for them.

Mr. Mitchell said that the centralization of all War Loan activities in one person who is actually linked with the War Finance Committee will result in a mutual saving of time and effort for both the Payroll Savings Division and the 10,000 companies operating under the new plan.

# ANALGESIC SPASMOLYTIC SEDATIVE

## New York Veterans Lack Psychiatric Care, Report Shows

THE New York City Committee on Mental Hygiene of the State Charities Aid Association made public on September 21 a summary of a report of an extensive study of 623 men who had been rejected for or discharged from the armed forces for neuropsychiatric reasons (nervous and mental handicaps or disabilities).

The purpose of making the study was to determine the kinds and extent of care and help needed for their rehabilitation, and the facilities available to meet such needs.

The study, based on an investigation of a typical sample of 314 rejected and 309 discharged men, revealed that only a small percentage of them are receiving needed psychiatric care, and that community facilities for such care are wholly inadequate to the needs.

The outstanding finding of the report was that among the 623 men studied, 492, or about 80 per cent, were found to need some form of psychiatric help.

However, only about 25 men (5 per cent) were getting it. One factor in the problem is that the majority of the men are neither aware of their need of psychiatric help nor recognize its value. Of the 492 men needing such help, only 123, or 25 per cent, understood their need of it. The lack of facilities to provide such help is reflected in the fact that of 123 men who knew that they needed psychiatric help and wished to have it, 17.5 per cent, or only about 25 men, were actually receiving it.

These percentages, when applied to the entire group of estimated neuropsychiatric rejectees and discharges for New York City (135,500), indicate that of these 103,000 need some sort of psychiatric help; that 27,000 want help, and of these only about 5,400 are receiving it, though they are eager for it and need it badly.

Of the 314 rejected men studied, 257 needed psychiatric help; 151 needed organic medical and surgical treatment; 139, vocational counsel and assistance; 46, neurologic; 24, family case work; 15, group or recreational; and 15, educational. Some of the men required more than one kind of treatment or help.

The investigation of 309 discharged men showed 235 needing psychiatric help, 184 medical and surgical treatment, 166 vocational, 24 neurologic, 31 family case work, 10 group or recreational, and 46 educational.

The group studied were New York City residents and the implications of the survey were stated in terms of estimated present and prospective rehabilitation needs in this city. The survey is considered to have national as well as local significance, and the report has been submitted to the War and Navy Departments, the U.S. Public Health Service, National Selective Service, Veterans' Administration, the Department of State, the Federal Security Agency, the American Red Cross, and various other officials, agencies, and individuals concerned with this problem.

The study was made under a grant to the New York City Committee from the Commonwealth Fund and was carried out under the direction of a Subcommittee on Psychiatric Needs in Rehabilitation,

comprising Dr. Lawrence S. Kubie, Chairman; Ethel L. Ginsburg, Assistant Director, Veterans' Service Center; Dr. Marion E. Kenworthy, New York School of Social Work; Samuel J. Kopetzky, Col., (MC), Medical Director, New York City Division, Selective Service; Marian McBee, Executive Secretary, New York City Committee on Mental Hygiene; Dr. Robert B. McGraw, Chief of Clinic, Department of Psychiatry, Vanderbilt Clinic; Harry N. Rivlin, Ph.D., Associate Professor of Education, Queens College; and Alice J. Weber, Regional Representative, Bureau of Public Assistance, Social Security Board.

Dr. Sol W. Ginsburg was medical director of the study and wrote the report. The investigation was carried out by a staff under his direction, comprising Louisa Blaine and Raymond Franzen, Ph.D., research consultants; Clara Rabinowitz and Rae L. Weisman, psychiatric social workers, and Ruth Valentine, Ph.D., psychologist.

The report disclosed that from October, 1940, through June, 1944, in New York City alone, 291,704 men were rejected for service in the armed forces for all causes. Of these, 87,500 were rejected on neuropsychiatric grounds, or about 30 per cent.

According to Army figures which have released, the report stated, of the one and a half million men who have already been discharged from the Army the approximate percentage of discharges on neuropsychiatric grounds would be 40 to 45 per cent of the total discharged. New York City contributes about 8 per cent of the armed forces, and the neuropsychiatric discharges from New York City total about 48,000 and both the discharges and rejectees about 135,500.

The magnitude of the problem presented by men rejected for service in the armed forces because of neuropsychiatric disabilities and by those discharged for such reasons is now well recognized by those close to the problems, the report stated, but it is far from being understood by the general public. It is a conservative estimate that up to July, 1944, there have been 135,500 such neuropsychiatric discharges and rejectees in New York City.

Little has been known as to exactly what this group of men need in the way of special psychiatric and other services, as to what civilian facilities are or can be made available to satisfy this demand, and as to what new services or enlarged services are needed. This study was made to attempt to answer these and related questions. The investigation was made possible through the courtesies extended by Col. Samuel J. Kopetzky.

The need, the report states, is in sharp contrast to the situation with respect to the available resources for the common types of medical and surgical treatments.

Of the veterans who want help (75 per cent of the rejectees and 74 per cent of the discharges) between 80 and 90 per cent are receiving the forms of medical and surgical aid they require as against only 17.5 per cent of the neuropsychiatric cases who are getting the treatment they need. Nothing could make clearer than this the inadequacy of existing facilities for psychiatric treatment in the community, the report stated.

## Harvard Medical School Opened to Women

**H**ARVARD University on September 25 opened the doors of its Medical School to women for the first time since the school was founded 162 years ago. Closing a long fight, the board of overseers of Harvard College approved a recommendation of the faculty of the Medical School that women be eligible for admission. The recommendation was approved two months ago by the Harvard Corporation and will become effective in the fall of 1945.

The Medical School was one of the few major medical schools to exclude women.

Harvard has for several years been admitting women to several of its other graduate schools.

The question of admitting women to the Medical School had been discussed since 1847, but the war brought the issue into a new light as the need to replace physicians going into the armed forces became apparent.

The medical school faculty voted last year to admit women, but the recommendation was turned down by a six-to-one vote of the Harvard Corporation. The faculty renewed its proposal early this year.

During the last war a proposal was made that women students of Radcliffe College be permitted to study medicine at Harvard, but nothing came of it.

In 1872 the faculty turned against a proposal by Dr. Marie Elizabeth Zakezewska, founder of the New England Female Medical College, that Harvard take over that school.

A survey of fifteen leading medical colleges in seven cities, recently reported in the *New York Times*, showed only a slight increase in enrollment of women at nine schools. The other six report enrollment at the level of previous years.

## Medical Prize Awarded

**T**HE Institute of the Aeronautical Sciences recently announced award of the annual John Jeffries prize for contributions to aeronautic medical research to Sir Harold E. Whittingham, Director General of the medical services of the Royal Air Force.

Since his graduation from Glasgow and service in Iraq and India in the last war, Sir Harold has

been the initiator and organizer of medical research for the RAF.

The award was made by a committee consisting of the Director of Research, National Advisory Committee for Aeronautics, and the presidents of the National Aeronautic Association, the Air Transport Association, the Aero Medical Association, the Institute, and the Aeronautical Archives.

## Admiral Butler Dies

**R**EAR ADMIRAL CHARLES ST. JOHN BUTLER, U.S.N., retired, authority on tropical medicine and seasickness, died at his home in Bristol, Tennessee, on October 7.

Born in Bristol in 1875, Admiral Butler entered the Navy medical service in 1900. He was the author of a number of scientific papers and spoke before many medical gatherings. His last assignment before he retired in 1939 was that of chief administrative officer for the United States Naval Hospital in Brooklyn.

Admiral Butler, who received his M.D. from the University of Virginia in 1897, was commanding officer of the Naval Medical School, Washington, D.C., from 1921 to 1924, and again from 1927 to 1932; of the United States Naval Hospital, Brooklyn, 1932-1935; of the Naval Medical Supply Depot, Brooklyn, 1935-1936; of the Naval Medical Center, Washington, D.C., 1936-1938.

In 1935 Admiral Butler was president of the New York Society of Tropical Medicine, and in 1940-1941 of the American Academy of Tropical Medicine.

## Typhus Commission Medal Awarded to Five

**T**HE United States of America Typhus Commission Medal has been awarded by order of the President to Dr. Abdel Wahed El Wakil, Egyptian Minister of Health, and to three British Brigadiers of the Royal Army Medical Corps for the help they have given representatives of the Commission in investigating typhus fever in the Middle East and southern Italy. The members of the Royal Army Medical Corps are Brigadiers John S. K. Boyd, George B. Parkinson, and Rudolf W. Galloway.

Dr. Wakil was cited for his close cooperation with the Commission at Cairo which resulted in benefit

to the military forces; Brigadier Boyd's citation was for his cooperation in arranging for the distribution of typhus vaccine through the Middle East; and Brigadier Parkinson and Brigadier Galloway were cited for their help in preventing the spread of typhus in southern Italy.

Brig. Gen. Leon A. Fox, USA, was also awarded the medal, for his service as director and field director of the United States of America Typhus Commission, which brought the epidemic in Southern Italy under control within a month.—*Release from the Office of the Surgeon General, Sept. 15, 1944*

## County News

### Albany County

Dr. John E. Heslin, of Albany, was chosen president-elect of the Western New York and Ontario Urological Society at the meeting of that organization held in Buffalo in September.

### Chautauqua County

Dr. Percy S. Pelouze, of Philadelphia, addressed

the fall meeting of the county society on September 20 at the Newton Memorial Hospital, Cassadaga.

Dr. Pelouze, formerly assistant professor of urology at the University of Pennsylvania and consulting urologist at the Delaware County Hospital, is at the present time serving as special consultant for the

U.S. Public Health Service and for the past two years has devoted a major portion of his time to lectures and consultations at military hospitals and the U.S.P.H.S. Rapid Treatment Center.

Dr. Pelouze is the author of many scientific articles, as well as several books, two of which are *Gonorrhea in the Male and Female*, and *Office Urology*.

During the next two months, he will speak before a number of county medical societies in New York State. He addressed the annual meeting of the Eighth District Branch of the New York State Medical Society.

He is now a member of the boards of directors for the American Social Hygiene Association and the American Neisserian Medical Society.

Also appearing on the county association's program was Miss Ruth G. Hall, of Albany, member of the State Committee for the Procurement and Assignment of Nurses, who discussed the functions of the committee in connection with recruitment of nurses for the armed forces and for work in civilian hospitals in critical areas.

The session began with dinner at 1:00 P.M.\*

#### Dutchess County

A regular meeting of the county society was held in the new pavilion of the Hudson River State Hospital, Poughkeepsie, Wednesday, October 11, at 8:00 P.M.

The scientific session was "Present Day Advances and Treatment of Venereal Diseases," by Dr. P. S. Pelouze, of the Pennsylvania Medical Society and author of several books on venereal disease.

#### Erie County

The new secretary-treasurer of the Western New York and Ontario Urological Society is Dr. George E. Slotkin, of Buffalo, who was elected at the Society's meeting held in Buffalo on September 15.

#### Franklin County

Tribute was paid to the memory of the late Dr. Edward Livingston Trudeau, first president of the Saranac Lake Society for Control of Tuberculosis, at the fortieth anniversary celebration of the National Tuberculosis Association held the week of September 15.

The local society, organized in 1907, was the first of the smaller groups founded. It will publish its thirty-eighth annual report next January.

Dr. Edward R. Baldwin occupied the chair at the organization's first meeting and has since served as a member of the executive board of the Society.

Dr. John N. Hayes is now president and Dr. Francis B. Trudeau is vice-president. Dr. Daniel M. Brumfield is a member of the executive committee.

Dr. Hugh M. Kinghorn is chairman of the district nursing committee and Dr. Baldwin of the ways and means committee.

A regional Christmas Seal conference of representatives from five northern counties was held in connection with the celebration. Attending were state and local workers, executive secretaries, and board members from Franklin, Essex, Clinton, St. Lawrence, and Hamilton counties.

Mrs. Marie Warner Anderson, seal-sale campaign director of New York State, and George J. Nelbach, executive secretary of the State Charities Aid Association, were in charge of the conference.\*

#### Kings County

A special mass meeting of the Physicians Guild of Kings County was held October 10 at 9:00 P.M. at the Biltmore in Brooklyn. The program consisted of four lectures: "The Functions and Operations of the Medical Practice Committee—New Compensation Laws," by Dr. Francis M. Conway, chairman of the Medical Practice Committee; "Relationship of the Labor Department to the Physician," by A. Goodman, Deputy Commissioner of Labor; "A Comprehensive Analysis of the Pending Federal Health Insurance Legislation," by Louis H. Solomon; and "United Medical Service," by Dr. Frederick E. Elliott.

The physicians of Kings County and their wives were invited to the meeting.

. . .

The first meeting of the executive committee of the Pediatric Section of the Medical Society of the County of Kings for the current year was held on October 9, at the home of Dr. A. M. Litvak.

Several scientific sessions have been planned for this year, the first of which was held on October 23, at 8:30 P.M. at the Kings County Medical Society. Dr. James E. Perkins of the New York State Health Department spoke on "Epidemiology of Poliomyelitis," and Dr. William B. Snow, of Manhattan, discussed "Therapy in the Acute and Convalescent Stages of Poliomyelitis." The medical profession has been cordially invited to this and all subsequent sessions.

The officers for the current year are Dr. Abraham M. Litvak, president; Dr. Henry Rascoff, vice-president; Dr. Harold Levy, secretary; and Dr. Samuel K. Levy, treasurer.

. . .

A new ceremony was added to the eighty-sixth commencement exercises of the Long Island College of Medicine at the Brooklyn Academy of Music on September 28 with the presentation of the first Alumni Medal for Distinguished Service to American Medicine to Dr. Robert L. Dickinson, world-known gynecologist, who graduated from the college in the class of 1882.

Dr. Frank L. Babbott, chairman of the Board of Trustees and former president of the college, made the presentation of this first award, which is a medallion bearing the head of Hygieia, goddess of health. This alumni-achievement medallion, Dr. Babbott said, has been established to honor graduates of the college who have made notable contributions to American medicine.

Dr. Dickinson has distinguished himself as a leader in gynecology, obstetrics, in teaching, and in research and in medical arts. He is interested in problems of human health to which problems he has made many contributions. At the present time Dr. Dickinson is in charge of a studio of medical art at the New York Academy of Medicine. Dr. Dickinson's achievements in research, in medical arts, and in teaching represent a distinguished career of sixty-two years. He still is actively at work on creative endeavors.

Models have been made for medallions bearing the heads of Hippocrates and Aesculapius, which will be used for subsequent recipients of the award. The college will retain a replica of each award as it is made, for display in the main administration building.

# *The Answer*

To Some of Your Secondary Anemia Problems . . .

---

## *When Iron Alone is Indicated:*

In simple secondary anemia, no hematurin other than iron is required. It is generally accepted that iron in ferrous form is more effective, can be used in smaller dosage, and has fewer side-effects than other forms of iron. Tablets Ferrous Sulfate Exsiccated Squibb contain 3 grains—the U.S.P. dose equivalent to 5 grains of the hydrated salt. Supplied in bottles of 100 and 1000.

## *When Iron and B Complex are Indicated:*

For such patients, Hebulon\* Capsules may be advantageously prescribed. These easy-to-swallow gelatin capsules contain 2 grains exsiccated ferrous sulfate, 50 U.S.P. units Vitamin B<sub>1</sub>, and the B complex factors present in a liver extract derived from 16 grams fresh liver. Supplied in bottles of 100, 500, and 1000 capsules.

\* Hebulon is a trade mark of F. R. Squibb & Sons

### New York County

Dr. Oswald T. Avery, member of the staff of the Rockefeller Institute for Medical Research, received the New York Academy of Medicine Gold Medal on October 5 for his discoveries made during thirty years of research on the pneumococcus or pneumonia germ. Dr. Arthur Freeborn Chace, president of the Academy, presented the medal to Dr. Avery at a brief ceremony in the auditorium of the Academy building.

This year Dr. Avery has studied the transformation of one type of pneumococcus into another, and has "isolated the 'transforming principle' as a thymonucleic acid," a discovery which, according to the citation, "has very far-reaching implications for the general science of biology."

Since 1930 the Academy has awarded six gold medals for distinguished service to medicine. The last presentation was made in 1938 to Dr. Béla Schick, discoverer of the Schick test for diphtheria and the toxin-antitoxin serum for diphtheria prevention.\*

. . .

Robert E. Dineen, State Superintendent of Insurance, and the New York Board of Social Welfare announced on September 21 their joint approval of a certificate of incorporation for the Health Insurance Plan of Greater New York, approval required under the Membership Corporations Law.

. . .

The stated monthly meeting of the county society was held on October 23 at 8:15 p.m. at the New York Academy of Medicine. The executive session was followed at 9:00 p.m. by a scientific session, consisting of four lectures: "Relationship of the Practicing Physician to Industry," by Frederick H. Shillito, chairman of the special committee on industrial medicine of the county society; "Federal-State Rehabilitation Program for Disabled Civilians," by Dr. Dean Clark, Senior Surgeon (R), U.S.P.H.S., Chief Medical Officer, Office of Vocational Rehabilitation, Washington, D.C.; "What Industry Expects of the Doctor," by Dr. Victor C. Heiser, medical director, National Association of Manufacturers; and "Psychiatry in Industry," by Dr. Charles C. Burlingame, psychiatrist-in-chief of the Institute of Living, and chairman of the subcommittee on psychiatry of the National Association of Manufacturers.

### Oneida County

Dr. Esther L. Moeller, who was the only woman in the class of 1942 at Albany Medical College, has returned to New Hartford, her home, to practice general medicine.

Her husband, Dr. A. DeWitt Brown, established an office in New Hartford last December.

Dr. Moeller received her premedical education at Barnard College, Columbia University, and after her graduation from medical college she served a year's internship in Memorial Hospital, Albany.

For the last year, she had been assistant resident in pathology and bacteriology in the Albany Hospital. She is a diplomate of the National Board of Medical Examiners.

Dr. Moeller and Dr. Brown were married December 29, 1942, a few months before they received their degrees together from the Albany Medical College.

### Ontario County

The fourth quarterly meeting of the county society was held at the Canandaigua Country Club, Canandaigua, on October 10. The business session was followed by dinner at 6:30 p.m. and a scientific session at 7:30 p.m.

Dr. Percy S. Pelouze, formerly of the department of urology of the University of Pennsylvania and now of the U.S. Public Health Service, spoke on "Gonorrhea—A New Control Program."

### Queens County

Dr. Robert M. Robbins, of Flushing, formerly Walton-Okaloosa County Health Officer in De Funiak Springs, Florida, is now assistant commissioner of Health in the Department of Health, Macon, Georgia.

### Rensselaer County

Dr. H. Jackson Davis, Chief Medical Officer of the State Department of Social Welfare, has been granted military leave from the department to accept a commission as major in the newly established Civil Public Health Division, U.S. Army Medical Corps.

Major Davis, who has been in State public health and social welfare services since 1930, left for Charlottesville, Virginia, on September 14 to begin his Army duties. The Civil Public Health Division will develop public health policies and practices in liberated and occupied countries in all war theaters, establish supervisory and liaison relations with local public health officials, and provide certain essential medical supplies in those areas.

Major Davis is a veteran of World War I, and holds liberal arts, medical, hygiene, and public health degrees from Stanford, Harvard, Yale, and Johns Hopkins Universities, respectively. Before joining the State Department of Social Welfare, he served in several administrative posts in the State Department of Health.

Major Davis is married and has two children. His home is in Nassau.

### Rockland County

Dr. Gerrit F. Blauvelt, Nyack, former president of the Rockland County Medical Society, observed his ninety-fifth birthday on August 1. Dr. Blauvelt is the sole surviving incorporator of the Nyack Hospital.

### St. Lawrence County

Dr. S. Pope Brown observed his fiftieth year as a doctor in Potsdam in June. He was graduated from the University of Pennsylvania, and started practicing medicine in Potsdam following graduation.

Dr. Brown served for twenty-three months during World War I, when he received a commission as first lieutenant. During his service he was raised to lieutenant colonel and spent thirteen months in France.

For the past sixteen years, Dr. Brown has served as St. Lawrence County coroner. He is a member of the Potsdam Hospital physicians' staff, the St. Lawrence County Medical Society, the State Medical Society, and the American Medical Association.\*

### Schuyler County

Dr. Raymond D. Fear, of Ithaca, district state health officer, discussed the poliomyelitis epidemic at

the luncheon of the Watkins-Montour Rotary Club at the Jefferson Hotel on September 15.

Dr. Fear said that in Schuyler County only 22 cases had been reported and that there were no serious cases and no deaths.

Dr. Fear was introduced by School Superintendent Irving D. Goodrich.\*

### Tioga County

Fifty years ago, on September 28, one of Owego's young men received his diploma for the practice of medicine in what is now known as the New York Medical College, Flower and Fifth Avenue Hospitals, in New York City.

Today that man, Dr. Louis D. Hyde, is still engaged in a branch of the medical profession in Owego. On September 27 Dr. Hyde participated in the commencement exercises at the hospital and received a gold diploma in honor of his anniversary.

Dr. Hyde has lived in Owego nearly all his life. He was graduated from the Owego Free Academy in 1888. He was valedictorian of his class in medical college and served an internship at the Middletown State Hospital. Dr. Hyde also served as a member of the staff of Glen Mary Sanitarium for six years.

Following his graduation in medicine, Dr. Hyde attended the College of New York Ophthalmic Hospital, where he was graduated in 1902. He later served as resident surgeon at this institution.

In 1903 Dr. Hyde returned to Owego and began his practice, which he is still carrying on.

Dr. Hyde served a term as president of the Tioga County Medical Society.

Two members of Dr. Hyde's class also practiced in the Village of Owego. Dr. A. W. Stoutenburg opened an office in the village and later died in Binghamton. Dr. Henry Merriam, who also practiced in Owego, now resides in Ithaca.\*

. . .

The Tioga county society held its fall meeting on Wednesday, October 4, at Seneca Lake. Dr. John B. Schamel was chairman of arrangements. Dr. Corbet Johnson, of Spencer, assisted Dr. Schamel with plans for the meeting.

Dr. Hiram Knapp, Jr., of Newark Valley, president of the society, conducted the business session.

Dr. Frederick Carpenter, of Waverly, dean of Waverly physicians, was the honor guest.

A number of Owego physicians attended the meeting.\*

### Washington County

The annual meeting of the county society was held on October 10 at 4:00 p.m. at the Court House in Hudson Falls. Following dinner at the Hotel Carlton at 6:30 p.m., a scientific program was given. Dr. Charles F. Rourke, president of the Medical Society of the County of Schenectady and attending physician (allergy) at Ellis Hospital, Schenectady, spoke on "The Allergic Skin." Dr. Robert D. Whitfield, clinical assistant surgeon at Albany Hospital, Albany, gave a lecture entitled "Ruptured Inter-vertebral Disks."

### Westchester County

"Laboratory research has discovered a new type of infectious organism between the bacteria and the viruses," Dr. Geoffrey W. Rake, director of the division of microbiology of the Squibb Institute for Medical Research, told the Westchester Medical Society at a meeting at New York Hospital, Westchester Division, on September 19.

Dr. Rake showed that lymphogranuloma venereum, psittacosis (commonly known as parrot fever), and trachoma are related diseases in so far as the type of infectious agent causing each is concerned.\*

. . .

Approval of the program for establishment of a county medical laboratory under the supervision of the County Health Department was given by the Westchester Medical Society on August 28.

The laboratory plan is proposed to include cities not in the County Health District, such as Yonkers, Mount Vernon, and New Rochelle, with costs apportioned, but approval from the cities has not yet been wholly given. Request for advice as to its views was made of the medical society recently by the Supervisors.\*

### Wyoming County

The Wyoming County Medical Society and the Livingston County Medical Society held a joint meeting on Thursday evening, October 22. The guest speaker was Dr. P. S. Pelouze, formerly of the University of Pennsylvania, now of the U.S. Public Health Service.\*

# Hospital News

## American Hospital Association's Institute on Hospital Purchasing in Chicago, November 13-17

**R**ECOGNIZING that the present pace of fighting in Europe may soon make possible more normal purchasing conditions, the Third Institute on Hospital Purchasing, conducted by the Council on Administrative Practice of the American Hospital Association, will be held at the Knickerbocker Hotel in Chicago, November 13 to 17.

Hospital administrators from among the 3,600 member institutions of the Association, and those concerned with hospital purchasing, will be present to receive and exchange information and methods at this conference, held with the cooperation of the Chicago Hospital Council and the Illinois State Hospital Association.

Developed to tie in wartime purchasing and post-war conditions with normal purchasing procedures, the program will give special emphasis to the pro-

cedures and problems of the small hospital. Morning sessions will be devoted to lectures on the theory and practice of purchasing and the organization of the purchasing department; afternoon seminars will feature open discussion on the purchasing of specific commodities; and evening round tables will clarify any questions remaining unanswered from the day's program, and give the registrant opportunity to present any specific problems from his or her hospital.

Director of the Institute will be Arden E. Hardgrove, chairman of the Purchasing Institute Committee and superintendent of Norton Memorial Infirmary at Louisville, Kentucky. His associate will be F. Hazen Dick, secretary to the Council on Administrative Practice of the American Hospital Association.

## Hospital Staffed by German Doctors Opened in Oklahoma

**T**HE Army Medical Department has established a separate prisoner-of-war hospital staffed with doctors and medical corps men of the prisoner's nationality. The first hospital, Glennan General Hospital, having a bed capacity of 1,700, has been established at Okmulgee, Oklahoma, for German war prisoners. American Army doctors are the chiefs of the medical services. Eight German physicians have been assigned to medical work. It is an-

ticipated the number will be increased to thirty or forty.

The Medical Department's new policy is in accord with the Geneva Convention Treaty, which stipulated that "It shall be lawful for belligerents reciprocally to authorize, by means of private arrangements, the retention in camps of physicians and attendants to care for prisoners of their own country."—*Release from the Office of the Surgeon General*

## What's in a Name? Confusion

**T**HE England General Hospital, the Army's medical center in Atlantic City, will be known hereafter by the full name of the man for whom it was named, Thomas M. England, a lieutenant colonel

who was a human guinea pig in the fight on yellow fever after the Spanish-American War. This move is to correct the impression, widespread and persistent, that the English operate a hospital here.

## Reconditioning News Letter

**A** NEW publication, *Reconditioning News Letter*, is now being distributed monthly by the Office of the Surgeon General to all ASF hospital commanders and service command surgeons. Its aim is to familiarize hospital personnel with new ideas, practices, and procedures connected with the reconditioning

program. Sources of the items published are reports made by inspecting officers from the Surgeon General's Office, chiefs of the reconditioning branches in service commands, medical officers, and others familiar with the program.—*Release from the Office of the Surgeon General, Sept. 15, 1944*

## At the Helm

Henry Hutton Landon, of New York, has been appointed superintendent of the Southampton Hospital, to succeed Miss Ellen Jacobsen, R.N., whose resignation has been announced. Miss Jacobsen has been superintendent since 1921.\*

George W. Peck, president of the Genesee Memorial Hospital, announces the appointment of Mrs. Ruth A. Mackey as superintendent of the hospital,

to succeed Mrs. Eva B. Berry, who recently resigned to take a similar position at Olean.

Mrs. Mackey, who assumed her new position October 1, is a graduate of the Columbia Hospital at Wilkensburg, Pennsylvania, and at present is a director of nurses at Tomkins County Hospital, Ithaca. She recently returned from Bolivia, South America, where she studied and investigated hospitalization.\*

(DRY REAGENT FOR URINE SUGAR)

*Time involved—30 seconds!**Acetone Test*

(DENCO)

*Time involved—one minute!*

Acetone Test (Denco) and its companion product Galatest (dry reagent for urine sugar) simplify "routine" urinalysis.

Acetone Test (Denco) detects presence or absence of acetone in urine in one minute. Color reaction is identical to that found in the violet ring tests. Trace of acetone turns the powder light lavender—larger amounts to dark purple.

## THE SAME SIMPLE TECHNIQUE FOR BOTH TESTS

1. A little powder      2. A little urine

*Color reaction instantly*

A carrying case containing one vial of Acetone Test (Denco) and one vial of Galatest is now available. This is very convenient for the

able at all prescription pharmacies and surgical supply houses.

*Accepted for advertising in the Journal of the A. M. A.*

[Continued from page 2386]

Herbert G. Willis, newly appointed superintendent of Corning Hospital, has taken over his duties in managing the community's hospital. Mr. Willis has been assistant superintendent of the hospital at Bradford, Pennsylvania, for the past five years.

. . .

Col. Robert H. Kennedy, former director of surgery at Beekman Hospital, New York City, and attending surgeon at the New York Post-Graduate Hospital, has been appointed chief of surgical service at Mayo General Hospital, according to an announcement by Colonel H. L. Krafft, commanding officer. Colonel Kennedy, a veteran of World War I, succeeds Col. Emery Neff, former surgical chief, who left for treatment at Percy Jones General Hospital.

The new surgical chief was called to active duty in World War II with the rank of lieutenant colonel in June, 1942. His first assignment was Chief of Surgical Service at Percy Jones General Hospital, which post he held until his arrival at Mayo. He was promoted to colonel on April 3, 1943.

Colonel Kennedy received his medical degree from the College of Physicians and Surgeons at Columbia

University in 1912.—Release from the Office of the Surgeon General, Sept. 15, 1944

. . .

William G. Illinger, for the past five years administrator of the New York State Institute for the Study of Malignant Diseases, Buffalo, has been appointed administrator of the White Plains Hospital, Alexander C. Nagle, president of the Board of Governors, announced.

Mr. Illinger took office October 1, replacing Thomas T. Murray, who has been superintendent-administrator at White Plains Hospital for the past four years.

Mr. Illinger has had fifteen years' experience in the field of hospital administration. He has attended New York University, the University of Chicago, and Cornell University, majoring in both business and hospital administration.

Mr. Illinger is an active member of the American College of Hospital Administrators, the American Hospital Association, New York State Hospital Association, and the Western New York Hospital Council. He has been active in civic and social welfare work in Buffalo, where he is currently vice-president of the board of directors of the Neighborhood House Association.\*

## Improvements

A \$16,600 centralized radio system was presented on August 24 to Halloran General Hospital, at Willowbrook, Staten Island, by Lt. Gen. James G. Harbord, retired chairman of the New York Chapter, American Red Cross, on behalf of the chapter. The ceremonies were held in the American Red Cross building on the post and were attended by high-ranking Army officers, officials of the Red Cross, and representatives of many organizations.

Preceding the first broadcast on the new system, Gray Ladies of the chapter distributed headsets to bed patients in all wards of buildings 2, 25, 27, and 29. The installation permits every patient to tune in a program of his choice from a radio station or from the hospital recreational auditorium or the chapel. Headsets on extension cords can be plugged into outlets in the wards. Of the twenty-one wards so equipped, sixteen were supplied by the New York Chapter, three by the Herman Goldman Foundation, and two by the High School of Music and Art. The installation in the chapel, whereby its services can be broadcast, was donated by the Women's Club of the Deaf.

In accepting the gift as head of the hospital, Brig. Gen. Ralph G. Devoe said:

"The benefit will be more than one of enjoyment. It will be in part therapeutic in that the soldier-patients will no longer feel they are apart from world happenings.

Mrs. Frank R. McCoy, the chapter's liaison representative at Halloran, explained the installation, and Mrs. Helen Thirlwall, Red Cross field director, was the announcer.

. . .

Modern equipment for the care and treatment of poliomyelitis cases has been ordered by the Wyoming Community Hospital of the Wyoming County Polio Foundation. So far the hospital has not needed any equipment and it is hoped it will not later on.

Included in the order is a \$350 hot-pack machine.

Mrs. Walter Solly, Attica, is the representative of the foundation.\*

. . .

Two additional iron lungs for the treatment of two sufferers from infantile paralysis—a 60-year-old man in Charles S. Wilson Memorial Hospital, Johnson City, and a 16-year-old Whitney Point girl in City Hospital—were obtained on September 1 by the Broome County Chapter, National Foundation for Infantile Paralysis, Inc.

Recently, the local organization purchased an iron lung costing \$1,500 for Ideal Hospital but it has not been delivered, he said, because of the military demand for iron lungs. The organization also has purchased a Kenny hot-pack machine for Wilson Hospital at a cost of \$350.\*

. . .

Through the generosity of a Genevan who wishes to be anonymous and who is deeply interested in the security of the children of Geneva and vicinity, an iron lung has been purchased for Geneva General Hospital.

Hospital officials are very grateful for such a gift, which is much needed at this time, and were particularly pleased to know that so much interest is being shown in the health of the community.

It is understood that some local organizations and employees are considering the possibility of furnishing the hospital with additional equipment to make it as complete and up-to-date as possible.

Geneva Zonta Club has purchased accessories for the new iron lung, thereby guaranteeing additional comfort for the patient using the equipment. Accessories for the iron lung have to be purchased separately, and the Zontians felt that this would be a suitable and practical contribution from the club at this particular time.

presented to the hospital two de luxe electric hot plates to be used in the preparation of hot packs for the poliomyelitis patients.

Earl D. Auclair has offered his services as a volunteer to care for the iron lung servicing, not only for the present time but in the future.\*

. . .

Described as a great asset in the fight on infantile

paralysis, a machine called the "polio-washer" has been acquired by the Auburn City Hospital.

This machine is said to reduce the number of steps required in the treatment of poliomyelitis. Only three other hospitals throughout the country have these machines, according to Jerome F. Peck, Jr., acting superintendent of the hospital.

The machines are used in connection with the application of Sister Kenny's method of treating polio by hot packs and have been reported to have been quite successful.\*

## Newsy Notes

Although several workers had not completed their soliciting for the Ellenville Hospital Drive, the amount realized to August 28 was \$3,765.

Returns from workers from churches and organizations in Ellenville and nearby communities amounted to \$2,965; from Benjamin Lonstein and committee, from hotels, \$800. Mr. Lonstein's work was completed by Labor Day; he had full assurance that his committee would collect \$1,000, which is in excess of the sum collected in 1943.\*

. . .

Although there was \$1,564 in the Rhoads General Hospital telephone fund on July 31, it was predicted that the fund would be exhausted soon unless more contributions are received, Benjamin C. Grossman, treasurer, said on August 18.

Originally the free telephone service project promoted by the Jewish War Veterans had been offered only to bed patients. Because most of these saw their families fairly frequently, they made few long-distance calls. The service therefore was extended to all patients.\*

. . .

Workers of the Owego Factory contributed \$319 toward the payment for the iron lung recently installed in Tioga General Hospital by members of the Tioga County American Legion Auxiliary, who conducted a campaign to secure funds for the equipment.\*

. . .

Ten thousand dollars has been received in the eighteen-day drive for funds to pay the \$33,000 debt of the Margaretville Hospital.

The returns indicate that the total may run as high as \$30,000. This statement is based on the fact that about one third of those who subscribed last year had contributed the \$10,000.\*

. . .

One hundred and fifty-five thousand dollars was raised at a twenty-fifth anniversary dinner of the Israel Zion Hospital held recently at the Towers Hotel, Brooklyn. The dinner marked the beginning of the hospital's \$500,000 emergency campaign to complete and equip the new eight-story hospital annex, which will provide 220 additional beds and make possible the introduction of modern scientific equipment.

Guest speakers included Edward Lazansky, former Presiding Justice of the Appellate Division, Second District; Col. Samuel J. Kopetzky, chief of the medical division, New York City headquarters

of the Selective Service system; and former Assemblyman Albert D. Schanzer.\*

. . .

An employer-financed social security plan that will cost unionized hotels in New York City an estimated \$750,000 to \$900,000 annually and will provide benefits for 25,000 hotel workers was announced by Edward P. Mulrooney, impartial chairman of the hotel industry.

Retroactive to June 1, the 132 hotels covered by the plan will pay into the fund 6 per cent of their payrolls for the first six months and 3 per cent thereafter. The double payment for the first six months was directed by the three-man arbitration commission that formulated the plan so that a reserve might be accumulated quickly for the insurance fund.

Others on the commission headed by Mr. Mulrooney were Fred O. Cosgrove, vice-president of the Knott Hotel Corporation, representing the Hotel Association of New York City, and Jay Rubin, president of the New York Hotel Trades Council, American Federation of Labor. Their approval of the plan was unanimous, according to Mr. Mulrooney.

The majority of the hotels in the city, including all the large ones except the Waldorf-Astoria and the Lexington, are included under the plan, which, Mr. Mulrooney said, would become part of the current contract between the hotels and the union in effect until June 1, 1946. He estimated that 80 per cent of the city's hotel workers would benefit. Under the new social security arrangement union members in good standing will receive a life insurance policy, sickness and accident insurance, and family hospitalization.\*

. . .

Plans to expend \$209,000 for additional state care of poliomyelitis victims stricken in an epidemic which has claimed 2,809 reported persons were announced on September 2 in Albany.

Governor Dewey said the money would be added to the regular appropriation of the State Health Department and would be used chiefly to enlarge facilities of the New York Reconstruction Home at West Haverstraw. It is planned to add 100 beds to the 130 now available there for the aftercare of stricken children.

Infantile paralysis patients beyond the acute stage may be cared for by the state under provisions of the Physically Handicapped Children's Act. If more than 21 years old, they may receive treatment under provisions of the Shaw Act.

## BRITISH MILITARY PSYCHIATRIST TO GIVE SALMON LECTURES

Brig. Gen. J. R. Rees, consultant psychiatrist to the British Army, will deliver the Salmon Lectures for 1944 at the New York Academy of Medicine on three successive evenings—November 20, 21, and 22 at 8:30 P.M.

The Salmon Committee on Psychiatry and Mental Hygiene, appointed by the Council of the New York Academy of Medicine, annually invites an outstanding specialist in the field of psychiatry, neurology, or applied sciences, who has made the greatest contribution to his specialty during the preceding year, to deliver the lecture series.

As a captain in the R.A.M.C. in the first World War, Brigadier General Rees saw service in Belgium, France, Mesopotamia, and North Persia. He was formerly neurological specialist, Ministry of Pensions, and medical superintendent, Bowden House. He now holds the post of medical director, The Tavistock Clinic (The Institute of Medical Psychology).

The subject of Brigadier General Rees's lecture on November 20 will be "The Frontiers Extend," in which he will review the experiences of the war in so far as they open up new psychiatric responsibilities. He will trace the developments of the new social psychiatry and of new practices in selection and placement engendered by the realism of the war period. He will present material to show that war-time priorities are prophylaxis in the building up of mental health.

On November 21, the speaker's subject will be "Opportunities Emerge." Asserting that training methods, morale, and disciplinary problems have been matters of urgency in the Army, as indeed they have been also in civilian life, Brigadier General Rees will discuss the fact that men and women of all kinds and qualities challenge our psychiatric skill

and that war psychiatry has contributed to the women's services, to adult education, and to re-socialization of the sick and maimed, as well as in matters of intelligence and aptitude testing and selection of officer candidates and other special groups on the basis of studies in character, personality, leadership, and stability.

On November 22, in the "The Way Ahead," Brigadier General Rees will survey both the old and new responsibilities of psychiatry, in which he will indicate that individual breakdown is perhaps less important than group breakdown.

Following these lectures at the Academy of Medicine in New York, Brigadier General Rees will present condensations of the three Salmon Lectures in New Orleans, San Antonio, Houston, Los Angeles, Boston, and Montreal.

The Salmon Committee on Psychiatry and Mental Hygiene, which is sponsoring these lectures, includes in its membership the following: Dr. C. C. Burlingame, *Chairman*, psychiatrist-in-chief, The Institute of Living, Hartford, Connecticut; Dr. Samuel W. Hamilton, Division of Mental Hygiene, U.S. Public Health Service, Washington, D.C.; Dr. William Healy, consulting director, Judge Baker Guidance Center for Childhood and Youth, Boston; Dr. Adolph Meyer, psychiatrist-in-chief, emeritus, of the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore; Dr. Edward A. Strecker, Department of Psychiatry, University of Pennsylvania Medical School, Philadelphia; Dr. Edwin G. Zabriskie, professor of clinical neurology, Columbia University Medical School, New York City; Dr. Arthur F. Chace, president, New York Academy of Medicine, New York City; Dr. Herbert B. Wilcox, director, New York Academy of Medicine, New York City.

#### VD EDUCATION FILMS

The motion-picture films "*Magic Bullets*" and "*To the people of the United States*," for use in venereal disease education, are now ready for distribution.

"*Magic Bullets*" is available in a three-reel version of the famous Warner Brothers feature length film starring Edward G. Robinson and depicting Ehrlich's discovery and early use of arsenical drugs in the treatment of syphilis. The U.S.P.H.S. version retains the scientific and medical story of the original eleven-reel film. Review prints have been sent to State Health Officers on fifteen-day loan. The film can be purchased from DeLuxe-Laboratories, 850 Tenth Avenue, New York 19, New York, at approximately \$27.50 for 16 mm. prints with reel and cans, and at approximately \$48.00 for 35 mm. prints.

"*To the People of the United States*," a two-reel educational film, starring Jean Hersholt, was pro-

duced by Walter Wanger, prominent Hollywood producer, and the California State Health Department, with the cooperation of the U.S.P.H.S. Through the courtesy of the California State Health Department, 16 mm. prints of this film have been sent to other state health departments. Additional 16 mm. prints can be purchased from Consolidated Film Industries, 959 Seward Street, Hollywood, California, at approximately \$20, with reel and cans. Since the film can be shown to general audiences, 35 mm. prints are being provided to health officers who request them for such use as they may desire. Additional 35 mm. prints can be bought from Consolidated at approximately \$35. Purchasers other than official agencies should remit with order.

U.S.P.H.S. authorization is not necessary for purchase of this film.—*VD War Letter, Aug. 30, 1944*

---

#### SOCIALIZED MEDICINE

Recently a business man accosted a friend and said: "Well, doctor, I see where they are going to socialize your business under the Federal Security Act." The doctor, who had spent his life helping the ill and afflicted in his community, regardless of their financial circumstances, said: "Oh, no, my friend, they are going to socialize you. When the federal government takes six per cent of your earnings and six per cent from your employer on wages paid you up to a specified amount, tells you what doctor to go

to, when, and where, you will be getting the benefits of socialism, not me. When that day comes I will go back to pipe fitting, which is just working with a different kind of pipes than those in a human."

Yes, it's the public, not the doctors, that would suffer from politically appointed physicians. There would no longer be incentive for the better doctors to carry on. An independent pipe fitter would have more future than a socialized doctor.—*Editorial in the Riverhead (N.Y.) News*

# Woman's Auxiliary

## To the Medical Society of the State of New York

### County News

**Fulton County.** The members of the Fulton and Montgomery County auxiliaries to the medical societies of these counties held a dinner meeting at the Towers, in Amsterdam, September 19. The State President, Mrs. Carlton Wertz, of Buffalo, was guest speaker. She was introduced by Mrs. Joseph Thompson, of Gloversville, president of the Fulton County Auxiliary.

Mrs. Wertz told of the tireless efforts of doctors' wives in assisting in the care and treatment of poliomyelitis patients. She added that with the consent of the Erie County Medical Society an "Infantile Paralysis Day" was held. The women of the auxiliary procured scientific speakers for the doctors, and others for the lay people. Many notes of thanks were received for the programs.

Mrs. Wertz added that in this time of stress, doctors' wives can be of the greatest assistance to their husbands in carrying on their work. She also asked that auxiliary members be especially considerate of the women whose husbands are in service.

This meeting was enjoyed so much that the two county auxiliaries agreed to hold another joint session at a later date.

Many thanks to Betty Wertz for a most pleasant evening!

**Nassau County.** On Tuesday, September 19, the auxiliary had an executive board meeting. Mrs. Louis Van Kleeck presided at the meeting. Business for the coming year was discussed and the program was presented. The program is as follows:

September 29, 1944—Membership tea.

October 31, 1944—Meeting. The topic was "Nurse Recruitment."

November 28, 1944, 8:00 P.M.—Meeting. The topic, "United Medical Service."

December 12, 1944, 8:00 P.M.—Christmas party.

January 30, 1945, 8:00 P.M.—Joint meeting with Medical Society at Mercy Hospital R.U.C. The speaker will be a Supreme Court Justice.

February 27, 1945, 8:00 P.M.—Meeting. The topic, "Seeing Eye Dog."

March 27, 1945, 3:00 P.M.—Meeting. The topic, "Cancer Institute."

April 24, 1945, 8:00 P.M.—Meeting. The speaker will be Dr. Joseph Lawrence.

May 29, 1945, 8:00 P.M.—Annual Meeting.

June 26, 1945, 1:00 P.M.—Luncheon.

Plans for the membership tea were discussed at the executive board meeting. The speakers at the tea were Dr. Austin B. Johnson, president of the

Nassau County Medical Society, Dr. Louis Bauer, trustee of the A.M.A., Dr. E. K. Horton, and Dr. Louis A. Van Kleeck. Entertainment was furnished by Miss Gertrude Bary, pianist, and Miss Catherine Molter, harpist. Mrs. August Fink, membership chairman, was in charge of arrangements.

The members had a box lunch after the meeting, which took place at 10:00 A.M. at Nassau Hospital in Mineola. At 1:00 P.M. cancer dressings were made under the supervision of Mrs. Anne Moore, consultant nurse for the Nassau County Cancer Committee.

**Orange County.** The first executive meeting of the year was held at the Mitchell Inn in Middletown on September 21. The reading of the annual minutes showed that there were sixty-four paid-up members, and of these there are twenty-six members whose husbands are in service. From records available, members of Orange County had given about 15,000 hours of war work. The new president, Mrs. Harry L. Chant, presided.

**Schenectady County.** The Schenectady County Woman's Auxiliary has elected the following women as officers for the coming year: Mrs. Arthur Congdon, president; Mrs. William J. Jameson, president-elect; Mrs. Alfred Grussner, first vice-president; Mrs. Marcellus Clowe, second vice-president; Mrs. Edward O'Keefe, treasurer; Mrs. Ralph Hotchkiss, historian; Mrs. James Blake, corresponding secretary; Mrs. Roland Faulkner, recording secretary.

The election was held at the closing meeting at the lovely home of Mrs. F. Leslie Sullivan on Sunnyside Road in Scotia.

The first fall meeting was held October 24 at Hotel Van Curler in Schenectady. Dr. Charles Rourke, president of the county medical society, was the speaker.

The executive board meeting was held September 21 at the home of Mrs. Arthur Congdon.

**Suffolk County.** Suffolk County Auxiliary met on August 3 for dinner in the Shoreham in Sayville. Mrs. E. R. Hildreth presided in the absence of the president, Mrs. S. A. Arnold. Reports were made by all the committee chairmen, and a stirring debate followed the business meeting. The topic of the debate was the Murray-Wagner-Dingell bill. Mrs. Grover Silliman spoke in defense of the bill and Mrs. George Bergmann spoke in opposition. The discussion was so lively that further debate had to be postponed until the next meeting, when Mrs. L. H. Kice, the State legislative chairman, will be the guest speaker.

### FEW WOMEN ENROLL IN MEDICAL SCHOOLS

A recent survey of 15 leading medical colleges in seven cities over the country shows that the expected decrease in enrollment in 1945 will not be made up, in any large way, by women students. Only nine of the 15 schools reported a slight increase in feminine enrollment. Deans declined to admit

prejudice against women students, but a few indicated that they had little intention of encouraging women to enroll. The notable exception was at Tufts Medical School, Boston, where a spokesman reported the institution of a program to show women the advantage of studying medicine.

# *Lederle* VI-DELTA EMULSION

**A**LTHOUGH MORE POTENT in vitamins A and D than minimum strength Cod Liver Oil U.S.P. XII, this emulsion has—NO FISH-OIL TASTE—NO AFTER-TASTE.

VI-DELTA EMULSION is prepared from a concentrate of blended fish liver oils refined by a process which disposes of the "fishy" taste and after-taste. Natural citrus flavoring and high-grade malt extract are employed to impart a flavor as delicious as candy. Two teaspoonfuls of VI-DELTA EMULSION *Lederle* provide Vitamin A, 5000 U.S.P. XII units, Vitamin D (Vios-terol) 750 U.S.P. XII units.

*Lederle* VI-DELTA preparations come in five different dosage forms to meet the varied requirements of infants, children and adults:

Vi-Delta Emulsion *Lederle*  
Vi-Delta Liquid Concentrate *Lederle*  
Vi-Delta Clipsules *Lederle*  
Vi-Delta Capsules *Lederle*  
Vi-Delta Lentabs *Lederle*

Listen to the latest developments in research and practice—the new *Lederle* program, "The Doctors Talk It Over"—on the blue network every Friday evening.

# Not Lances, but a

# Lancet

He's a man of battle. He doesn't charge in with lance atilt—or its modern equivalent the bayonet, the Tommy gun, the Garand—but he's fighting for life, all the same. The lives of other men... and constantly at the risk of his own in those advanced dressing stations and field hospitals. Bombs lash down... shells burst... but he stays at his post.

Once in a while he has a moment to himself. A moment of relaxation... time for a cigarette... time for a Camel. With men in all the services, Camel is the favorite according to actual sales records.

# CIBA PHARMACEUTICAL PROD

SUMMIT, N. J.  
Medical Department

MEMORANDUM FROM: Medical Director  
TO: Advertising Manager

In view of recent lay publicity on the value of male hormone therapy in cardiovascular conditions and the male period of involution, many men may be approaching physicians asking for treatment, and while therapy may be justified in a certain percentage of cases, you surely know, only the physician can so determine. Naturally, it is contrary to Ciba policy to discuss such matters with the laity and we have very carefully referred all individuals seeking information to their physicians. It is quite evident however, that this publicity has aroused a great deal of interest.

I would suggest that you prepare copy, re-stating our attitude of such information to the laity and offer publication of such information to the laity and offer to the profession our most recent literature describing clinical results with androgenic preparations in these conditions.

NOTE:

*Run this memo as is - it is good,  
clear, understandable copy*

# N POSTPONEMENT OF PREGNANCY SEEMS EXPEDIENT

The management of the diabetic throughout gestation is too often

complicated by frequent exacerbations, and by sudden, unpredictable metabolic changes in tolerance.

Labor itself frequently proves difficult and prolonged because of the large size of the fetus.

And regardless of advances in therapeutic control, diabetes still accounts for a materially higher fetal and maternal mortality rate than in normal women.

For these reasons (and also for sound eugenics), many physicians advise anti-conceptual

practice. Ortho-Gynol Vaginal Jelly is a preparation distinguished for its

effectiveness, its safe action on extended use, ready miscibility, and ease of application.

## Ortho-gynol VAGINAL JELLY

Ingredients: ricinoleic acid, 0.7%, boric acid, 3.0%, oxyquinoline sulfate, 0.025%.

## DEPENDABLE ADJUNCT

In ANGINA PECTORIS • ARTERIOSCLEROSIS  
• PERIPHERAL VASCULAR DISEASES

# Carnacton

Carnacton is a biologically tested extract of highly vascularized and active diaphragmatic muscle with a high metabolic rate . . . providing dependable vasodilator and depressor benefits. Carnacton helps establish collateral circulation and promotes cardiovascular tone and vitality.

Ampuls of 1 cc. and 2 cc.—boxes of 12 and 50; vials of 30 cc. and 50 cc.  
for oral use. Also 2 oz. vials for injection. For brochure address Dept. N.

# UP

**VI-SYNERAL**  
FUNK-DURIN

POTENCIES SUBSTANTIALLY INCREASED •  
NO ADVANCE  
IN PRICE!

In line with our pioneering work in multiple vitamin-mineral therapy and with newer clinical research on vitamin requirements, Vi-Syneral now contains an average of 40 per cent more of important vitamins B<sub>1</sub>, B<sub>2</sub>, B<sub>6</sub>, niacinamide, calcium pantothenate, ascorbic acid, and alpha tocopherol (vitamin E).

*New Vi-Syneral Vitamin Potency*  
*...Vi-Syneral Special Group*  
(for middle-aged and aged)

<i>Each vitamin capsule contains:</i>	
Vitamin A	5000 U.S.P. U
Vitamin B <sub>1</sub>	3.5 Mg.
Vitamin B <sub>2</sub> (G)	3.5 Mg.
Vitamin B <sub>6</sub>	2 Mg.
Calcium Pantothenate	5 Mg.
Niacinamide	20 Mg.
Vitamin C	75 Mg.
Vitamin D	720 U.S.P. Units
Vitamin E (α-tocopherol)	4 Mg.
Vitamin B Complex	50 Mg. Yeast

Vi-Syneral also furnishes MINERALS: Calcium, Phosphorus, Iron, Iodine, Copper, Magnesium, Zinc, Manganese.

Vi-Syneral potencies have been similarly increased for the four other age groups: INFANTS and CHILDREN • CHILDREN and ADOLESCENTS ADULTS • EXPECTANT and NURSING MOTHERS.

## "NO, THE SPA IS NOT EXPENSIVE"

*... says the physician who  
knows its moderate cost.*

The overburdened wartime practitioner often feels that a stay at Saratoga Spa is indicated for a patient, but he believes the expense of treatment here would be too great.

Such is not the case, as is known to many practicing physicians who for years have been recommending regimens of restora-

tive treatment here for their patients with chronic cardiac, vascular or rheumatic disorders.

New York State erected extensive facilities at the Spa not to capitalize its famed mineral waters, but to safeguard them, to surround them with adjuncts best suited to their therapeutic use, for the benefit of all.

For professional publications of The Spa, and physician's sample carton of the bottled waters, with their analyses, please write  
W S McClellan, M D, Medical Director, Saratoga Spa,  
155 Saratoga Springs, N Y

# Seldom sick *but* never well

• Today, with our generously rationed American diet, there are few who develop frank vitamin deficiency syndromes.

But there is a great host of people who do not enjoy buoyant good health because they fail to obtain enough of these all-important accessory food substances.

*They are seldom sick but never well.*

For this great group, additional vitamins are necessary.

And what more convenient way is there to supply this need than to prescribe 'Avicap.'

One 'Avicap' a day supplies the minimum daily requirements of the six vitamins known to be essential in human nutrition.

'Avicap'—Registered Trademark

## *Avicap* Multi-vitamin Capsule

Each 'AVICAP' contains: Vitamin A . . . 5,000 U.S.P. units;  
Vitamin D...500 U.S.P. units; Vitamin B<sub>1</sub>...1 mgm.; Vitamin B<sub>2</sub>...2 mgm.;  
Vitamin C . . . 30 mgm.; Nicotinamide . . . 10 mgm.

NO. 2 OF A SERIES . . . "PREMARIN" THERAPY AT THE MENOPAUSE

## fully ORALLY ACTIVE

"Premarin" is fully orally active. Whenever estrogenic therapy is indicated, "Premarin" provides a highly effective and clinically proved medium for oral administration. Although highly potent, "Premarin" is exceptionally well tolerated and, being derived exclusively from natural sources, it has the desirable property of imparting a feeling of well-being. In "Premarin" the busy physician will find a medium for estrogenic therapy that is most effective, convenient and essentially safe.

"Premarin" is now  $\frac{1}{2}$  lower in cost (July, 1944)

# THE *Anatomy* OF A KEMP'S SUN-RAYED TOMATO

● Except for skin, seeds and core,\* all regions of this tomato are important to you in tomato juice. That's why we use the whole tomato, minus skin, seeds and core, for Kemp's Sun-Rayed brand Tomato Juice. Note proportion of three primary regions pictured above, left. Just right for finest flavor, high nutrition, rich red color and proper consistency. No ordinary field tomatoes these, but a special strain developed through 23 generations of tomato culture. We convert these tomatoes into Kemp's Sun-Rayed by our patented process which insures high retention of vitamins A, B<sub>1</sub> and C.

"IN UNION THERE IS

*Better  
creosote  
therapy*

- It is not surprising that physicians call CALCREOSE "a happy combination" In this popular cough preparation, the potent bronchial expectorant and antiseptic—creosote—is chemically combined with calcium thereby increasing creosote's bacteriostatic and bactericidal action up to three times, and (at the same time) insuring equally good absorption<sup>1</sup>
- Thus, Calcreose possesses all the well known benefits of creosote<sup>2</sup>, yet successfully masks its disagreeable odor and taste
- In many bronchial and respiratory affections, Calcreose will aid in lessening cough, diminishing expectoration, reducing its purulency, and deodorizing sputum (in fetor of bronchial secretions)
- Especially important Calcreose is freely tolerated, even in large doses, it causes no gastric irritation or nauseous reaction<sup>1</sup>

## SULMEFRIN

Squibb Stabilized Aqueous Solution Sulfathiazole Sodium (2.5%)  
with *dl*-desoxyephedrine hydrochloride (0.125%)

### FACILITATES DRAINAGE . . . IMPROVES VENTILATION . . .

In consequence of the vasoconstrictive action of desoxyephedrine hydrochloride.

Widely used for intranasal treatment of sinusitis, rhinitis, pharyngitis and laryngitis. Sulmefrin is mildly alkaline (pH about 9.0) and exerts locally the anti-bacterial action of sodium sulfathiazole which has almost optimum activity at this pH level.

Sulmefrin may be administered by spray, drops or tamponage. Supplied in 1-oz. dropper packages and 1-pint bottles. Solution is pink-tinted.

Sulmefrin is a trade-mark of E. R. Squibb & Sons.

**E. R. SQUIBB & SONS**

Manufacturing Chemists to the Medical Profession Since 1858

# A Rational, Systemic

**E**FFECTIVE treatment of chronic arthritis perforce must aim at correction of systemic as well as joint involvements.

Darthron, the fruit of years of clinical observation, is compounded especially for this purpose. In a single capsule it supplies massive dosage vitamin D plus adequate amounts of the other vitamins needed for optimal systemic improvement in chronic arthritis.

The antiarthritic value of vitamin D in maximal tolerated dosage is well established.<sup>1, 2, 3, 4, 5</sup> When this mode of therapy was first discovered, many of the other vitamins were still unknown. The more recent studies emphatically stress their importance in antiarthritic management.<sup>6, 7, 8</sup>

## SYSTEMIC INVOLVEMENT

Loss of weight  
Weakness  
Fatigability  
Anemia  
Neuritis  
Gastrointestinal disturbances  
Liver dysfunction  
Impaired carbohydrate metabolism  
Early arteriosclerosis

# Approach to Arthritis

Each capsule of Darthron presents vitamin D, 50,000 U.S.P. units; vitamin A, 5000 U.S.P. units; ascorbic acid, 50 mg.; thiamine hydrochloride, 2 mg.; riboflavin, 1 mg.; pyridoxine hydrochloride, 0.1 mg.; calcium pantothenate, 0.333 mg.; niacinamide, 10 mg.; mixed natural tocopherols, 3.4 mg.

## RATIONALE OF DARTHRON FORMULA

**Vitamin A** increases the tolerance for massive dosage of vitamin D

**Vitamin A** deficiency in the blood of rheumatic patients has been reported.

**Ascorbic acid (Vitamin C)** is essential for the normal development of intercellular material of connective tissue. Deficiency produces weakness, hemorrhage due to decreased cohesion of vascular endothelium, osteoporosis of bone, delayed wound healing.

**Thiamine** is essential for the physiologic activity of all tissues because of its role in carbohydrate metabolism. Deficiency causes weakness, loss of weight, fatigue, neuritis, gastrointestinal disturbances and impaired carbohydrate metabolism.

**Riboflavin** combines with phosphoric acid to form an oxidation enzyme essential for carbohydrate metabolism.

**Pyridoxine** plays a role in the utilization of unsaturated fatty acids and in hemopoiesis. It is effective in com-

bating hypochromic anemia, nervousness, weakness, difficulty in walking, and insomnia.

**Calcium Pantothenate** has been reported to be essential in maintaining the integrity of the central nervous system and the endocrine glands.

**Niacinamide** is an integral part of the coenzyme molecule essential in fermentation, glycolysis, and respiration. Specific in the pellagrous symptoms of dermatitis, in psychotic affections, and intestinal dysfunction.

**Mixed Natural Tocopherols (Vitamin E)** have been found useful in neuromuscular disorders and primary fibrositis.

Many of these conditions are commonly encountered in arthritis.

Physicians are invited to send for comprehensive literature and samples.

# DARTHRON

*for the Arthritic*

*"We're Both  
In Luck,"  
says Mommy*

You might say luck runs in the family—for the hearty, appetizing cereal this youngster gets is the same Heckers' Cream Farina his mother and grandmother knew as a "baby's first solid food."

But it's more than that these days. Enriched with Vitamin B<sub>1</sub>, niacin and nutritional iron, it's better than ever, now. And its heart-of-the-wheat goodness makes it a cereal the whole family goes for—and that helps simplify busy

mothers' problems. Quick to cook, quick to nourish, quick to digest, it's wonderful for baby, and satisfies the grown-ups too.

That's something to think about when you talk baby cereals to mothers. Their days are busy, their tasks many. You can recommend Heckers' Cream Farina as a grand baby cereal without hesitation—and do a favor for mother at the same time.

*The Grand Baby Cereal That The Whole Family Loves*

Would You Like a Package of  
Heckers' Cream Farina?

Won't you let us send you a sample of Cream Farina so that you will know at first hand how good it is? Simply mail your request to THE BEST FOODS, INC., Dept. 11, 88 Lexington Avenue, New York 16, N. Y.

# Protein Digestion *in* PREGNANCY

It is estimated that twenty-five to seventy-five percent of pregnant women develop hypochlorhydria during the course of their pregnancy.

Limited peptic digestion accompanying hypochlorhydria may lead to protein depletion of the mother and impaired growth of the fetus.

When hypochlorhydria is present, prescribe AMINOIDS\* for your patients. Because this protein hydrolysate product supplies pre-digested protein, the need for peptic digestion is largely obviated.

AMINOIDS contains the amino acids and peptides present in four high quality protein foods—beef, wheat, milk and yeast. One tablespoonful four times daily supplies 16 grams of protein as hydrolysate. Amounts up to and exceeding 100 grams daily may be assimilated with ease.

# Active vs. PASSIVE HYPEREMIA

In local inflammations, passive hyperemia or congestion retards healing. An increase in the circulation from the affected area is, therefore, desirable.

An important advantage of Numotizine in the treatment of inflammation is its ability to increase local circulation in both directions, thereby assisting the natural healing process.

The slow, steady release of guaiacol, beechwood creosote and methyl salicylate from the im-

proved Numotizine base stimulates local circulation and produces systemic analgesia for a period of 8 hours or more from a single application.

Numotizine is indicated in chest conditions, sprains, bronchitis, glandular swellings, furunculosis, etc.

**NUMOTIZINE**  
**THE PRESCRIPTION CATAPLASM**  
**NUMOTIZINE**

Supplied in 4, 8, 15 and 30 ounce resealable glass jars.

*Numotizine is ethically presented—not advertised to the laity.*

# ANATOMICAL SUPPORT

## for faulty

# BODY MECHANICS

*Patient of thin type of build —  
skeleton indrawn*

In conditions of faulty body mechanics, the nonuse of the abdominal muscles allows the pelvis to rotate downward and forward, bringing the sacrum up and back. There results an increased forward lumbar curve with the articular facets of the lumbar spine crowded together in the back. The dorsal spine curves backward with compression of the dorsal intervertebral discs and the cervical spine curves forward with the articular facets in this region closer together. Therefore, chronic strain of the muscles, ligaments and joints of the spine and pelvis occurs.

Camp Anatomical Supports have an adjustment by means of which their lower sections can be evenly and accurately brought about the major portion of the bony pelvis. When the pelvis is thus steadied, the patient can contract the abdominal muscles with ease and then with slight movement straighten the upper back.

*Relieving back strain and fatigue, due to faulty body mechanics is a feature of the Camp Support illustrated, and other types for Prenatal, Postnatal, Postoperative, Pendulous Abdomen, Visceroptosis, Nephroptosis, Hernia and Orthopedic conditions.*

## *of internal menstrual protection*

Primarily, the unique functional design of the Tampax vaginal tampon accounts for its numerous advantages—*anatomic, physiologic and psychologic.*

As one gynecologist<sup>1</sup> stated, at the conclusion of a study involving more than 2,300 cases of all types (many of whom employed Tampax over extended periods): "The patient does not even know that a tampon is present in the vagina if it is inserted sufficiently deep." He continued, "Many say they can forget that they are menstruating and so are without the disturbing annoyance they had every time they menstruated."

A general practitioner<sup>2</sup>, after studying 21 patients, remarked: "All patients were favorably impressed after using the tampons. Some said that they eliminated the chafing and itching caused by the usual external pads. Some said that

they eliminated a 'wet feeling' or 'unpleasant odor'. Others preferred them because they could indulge in sports with greater freedom."

And another specialist<sup>3</sup>, after observing 110 women (both single and married) who employed vaginal tampons throughout each period for from 1 to 2 years, reported that "because of the greater comfort experienced, 103 subjects preferred to continue to use the tampons through part or all of the menstrual period rather than to return to the use of the perineal pad alone."

Such opinions reflect the reactions of thousands of women in all walks of life who have experienced the advantages inherent in the Tampax method of menstrual hygiene.

# The New EPL *Cardiotron*

**A Portable, Direct-writing Electrocardiograph  
giving instantaneous standard readings**

We state that this device makes records which resemble those made by a photographic quality string galvanometer. Actually, in the case of certain types of wave forms, the fine stylus point on the EPL machine results in a much more accurate graphic copy of the electrical wave than is possible with the string machine. This is clearly illustrated in the reproduction of the chart made by a 7-cycle sine wave on the string machine, the EPL direct-writing machine, and the inertia-less cathode-ray oscilloscope (Figures 1-A, 1-B and 1-C). It is easily observable that the string does not accurately follow the peaks of the sine waves and adds a spike at the peak of each cycle. The true graph of this wave is shown on the cathode ray tube record; and it will be seen that the EPL direct-writer makes an identical graph.

This characteristic is additionally demonstrated in the reproduction above which shows the record made by an artificial heart device made by three methods. It may be noted that the shape of the "T" wave is slightly slurred in the case of the string, and that the EPL graph is precisely identical to the cathode ray record.

The two figures above represent records made on an abnormal heart, subject, male aged 52, by both string and EPL methods. The EPL graph is sharp and well defined.

**NOTE:** The new EPL Cardiogram Report Folder facilitates examination and filing, and assures absolute protection of the records.

At present, deliveries on AA-1 priority can be made in 10 weeks. We are accepting orders for delivery in rotation as soon as priority restrictions are lifted. Light in weight . . . 27 pounds, compact in size . . . 15½" x 11½" x 8¾". \$495.00.

### Insure Against Worry

If memory serves us as badly now as it has at times in the past, the following quotation is probably incorrect. But what of it?

"There was a doctor by name of Peck.

Fell down a well and broke his neck.

It served him right. He should have known

To treat the sick, and leave the well alone."

Medical care insurance, however, puts the doctor in his proper modern role of concern for the welfare of the apparently healthy before they become sick. If "health" insurance could assure health, which it cannot, many a doctor could take a vacation. If fire insurance could abolish fires, many a municipality could cut its budget. If life insurance could guarantee a state of living, things would be different from what they are.

Death and taxes are still with us, as the only certain events, in spite of every insurance policy that has ever been written. As Benjamin Franklin wrote to Leroy in 1789, "Our Constitution is in actual operation; everything appears to promise that it will last; but in this world nothing is certain but death and taxes."

Reverting to our text, doctors do not pro-

pose any longer to let the well alone. They have for years preached and fought for preventive medicine; they have preached and fought for really competent health departments staffed by properly trained doctors of public health; they have urged and helped to formulate laws for the enforcement of effective public health measures; they have sought by every means that human ingenuity and constructive imagination could devise to eradicate disease, to assist nature to function properly, to prolong life. While they have been principally concerned with the sick as the immediate necessity, they have not left the well alone. They have been thinking about the well, the healthy, and they have thought, among other thoughts: with all that can be done, people still become ill. Is there anything we can do that we haven't done before? Well, yes, there is.

We may not be able to keep all people well with the best of intentions and with all our knowledge, but we could possibly make some aspects of illness less disagreeable to think about or to experience. Maybe we could insure the cost of being sick, or, any-

how, part of the cost. That would knock Old Man Worry for a loop, maybe for two loops. Yes, doctors sometimes *think* in that language though they may speak to people in the office about echinococcus cysts, teleangiectic blood vessels, or avitaminosis.

"Yes, but—" said the yes-buffers. "You will break your ———<sup>1</sup> necks if you don't let the well alone."

<sup>1</sup> Since this JOURNAL enters the homes of respectable physicians copy has been censored.—*Editor*

## The World Do Move

From the *J.A.M.A.*<sup>1</sup> we excerpt the following editorial, in part:

"At its annual meeting in New York, October 4, the Governing Council of the American Public Health Association adopted a report favoring in effect a Federal plan of compulsory health insurance. The text of the adopted report appears elsewhere in this issue (page 441).\* This report, first prepared by a subcommittee, was approved after several amendments by the Association's Committee on Administrative Practice. The proposed medical service would be supported by social insurance, supplemented by general taxation, or by general taxation alone. . . ."

So far, nothing new has been added. And the fact that the A.P.H.A. should express itself on this question seems to us in no way remarkable. That is its right and privilege as a free American institution.

"The ratification of the report as amended came after extended debate in which there was opposition to the adoption and publication of the report as a stated policy of the Association."

We urge our readers to familiarize themselves with the full text of the report as published, because of its probable future significance to American medicine:

The *J.A.M.A.* says further:

"Those who opposed pointed out (a) that the administration of public health in the United States was by no means so universal or so generally adequate that public health departments in general were ready for this step, (b) that before the Association placed itself publicly on record in the terms of this report there should be consultation with the most interested professional groups, particularly the American Medical Association and the American Dental Association, and (c) that the publication of the subcommittee report, its approval by the

"What of it?" replied the non-yes-buffers, "if that will do any good."

"What the ———<sup>1</sup> do you know about the insurance business?"

"Very little, since we are doctors, but we can always ask, can't we? And if this thing can be done, we'll do it."

And there the matter stands. Insurance Against Worry, if you like. Backed by physicians. No cure, not even treatment for the ills that flesh is heir to, but an ever-present help in time of trouble. Insure now against Worry.

Committee on Administrative Practice, and the call for adoption in the Governing Council occurred within less than thirty days' elapsed time, although the subcommittee had been working on the report for a year."

Points *a*, *b*, and *c* when analyzed seem to indicate a tendency of the whole Council toward hasty action, the reason for which does not appear. The opposition certainly has raised questions which seem to demand careful consideration. Point *b* especially deserves, it would appear, more attention than it seems to have received. As far as we are aware, neither the A.M.A. nor the A.D.A. has indicated that it would necessarily go along with such a statement of policy, but we could be mistaken.

"The motion to adopt the report was made at the October 2 meeting of the Governing Council and was extensively debated at that time. Action was postponed until the October 4 meeting. At that time an amendment was offered to the motion to adopt. This amendment called for the Governing Council to receive this portion of the report of the Committee on Administrative Practice and to refer it to the Executive Board of the American Public Health Association with instructions to confer with the Board of Trustees of the American Medical Association and with the American Dental Association in an attempt to arrive at a statement which these three great professional groups could support. The amendment was lost by a standing vote approximately three-to-one after a voice vote had left the chair in doubt. The Governing Council then proceeded to vote on a motion to adopt the report; this vote was 49, Aye, and 14, No. The opposition to the adoption of the report was led by Drs. Walter A. Bierring, past president of the American Medical Association, Haven Emerson, and W. W. Bauer."

The proposal to confer seems such an obvious and reasonable one, so intimately related

<sup>1</sup> *J.A.M.A.*, Vol. 126, No. 7, Oct. 14, 1944, p. 434.

\* *Ibid.*

to public policy, good public relations, and to the public interest that one questions why it was not adopted. Sinister suspicions could and probably will be aroused by an action which could be merely over-hasty. We read further:

"Now what is the group that adopted this report? Of the 7,493 members of the American Public Health Association, 1,571 are Fellows. Only Fellows have a right to vote for governing councilors; the vote is conducted by ballot given to each Fellow when he registers at the meeting; Fellows not in attendance do not have a vote. The Governing Council consists of approximately one hundred members, of whom thirty are elected by vote of the Fellows, ten each year for three-year terms; the rest of the members of the Governing Council hold membership by virtue of being section officers or representatives of affiliated (mostly state) public health associations. Members of the Association other than Fellows can vote only on section affairs. The report on compulsory health insurance represents, therefore, the action of the subcommittee which prepared it, the Committee on Administrative Practice which approved it, and the forty-nine members of the Governing Council who voted in its favor."

Perhaps this small group of men really represents the attitude of the Association; perhaps not. It is not for us to say. But the report itself is public property, one more straw in the turbulent wind of destiny. And the method of its adoption can be scrutinized by anyone. Says the *J.A.M.A.*,

"Here is not a democratic practice in action; here is a shrewdly manipulated performance by full-time public officials, economists, bureaucrats. Most of the names of those on the subcommittee are those of men long committed to Federal compulsory sickness insurance and to Federal control of all matters in the health field.

"The American Public Health Association has an obvious right to express itself on any subject related to the public health. The rejection by the majority group of the proposal for consultation with medical and dental leaders indicates the attitude that may be expected of them if they should have control of the Washington bureaucracy that would dominate American medicine should their ideas become effective."

This observation seems somewhat justified by the reported facts and the procedure, but a person or group is often judged by the *last* thing he does not on the complete record. Action taken, as in this instance, seemingly in haste and in apparent disregard of good public and professional relations, may be repented at leisure. Only time will tell.

"Perhaps this step in which these men had leadership will be useful in serving notice once more on the medical, dental, nursing, pharmaceutical, and other professional groups as to the nature of the political manipulators in the fields of social security and public health whom the medical professions will be forced to combat."

Maybe so, maybe not. Education is a slow and costly process. Meanwhile, the world do move—and we with it.

## Respiratory Flora

Of all human ills the most frequent and widespread is the respiratory infection. Not only is it a potent cause of absenteeism, often at critical times and in critical situations, but it also may pave the way for secondary invaders, with serious sequelae. It is therefore of fundamental importance to learn how the respiratory pathogens gain entrance into the nasal and oral cavities. For such studies the newborn baby, who presumably enters the world with a sterile respiratory tract, is the ideal subject.

In corroboration of previous studies<sup>1</sup> recent investigations<sup>2</sup> show that nasopharyngeal cultures of newborn infants, taken up to sixteen hours after birth, were sterile in 80 per cent of babies. Between twenty-four and forty-eight hours after birth the oral cavities of about 50 per cent of babies remained sterile. After two to four days of age there no longer were bacteria-free respiratory tracts. Of particular interest

was the almost complete absence of such pathogens as the beta hemolytic streptococcus, pneumococcus, Friedländer's bacillus, and the influenza group of bacilli. Constant components of the respiratory flora were certain types of non-hemolytic streptococci and hemolytic staphylococcus aureus. Ultraviolet radiation and air conditioning simply delay the acquisition of the initial respiratory flora, for after two to four days there was no genuine difference in the flora in the noses and throats of infants in wards treated with irradiation and air conditioning from those not so treated. Clear evidence was presented, in the form of positive cultures, that the throat normally becomes infected before the nasopharynx, for the latter may remain sterile four days or longer after birth.

Since it has been demonstrated that the air of irradiated and air-conditioned nurseries contains few organisms as compared with the air of

untreated nurseries, it was important to ascertain why equality of infection was obtained in all nurseries in two days. Bacteriologic studies of the parturient canal revealed that this tract plays a minor role in the infection of the mouth or nose of the newborn baby.<sup>2,3</sup> In nursing infants the breast and other cutaneous areas of the mother which are necessarily in intimate contact with the baby's mouth and nose sometimes played a demonstrable role in the initial implantation of respiratory pathogens. The most common source, however, of the initial respiratory flora was proved to be the respiratory tract and fingers of those who were in most intimate contact with the baby. Cultures from fingers of nurses and from throats of nurses and doctors not infrequently revealed the very same type of organism with which the baby had been contaminated, generally a hemolytic staphylococcus from fingers, or a streptococcus from throats.

We gather from this meticulous bacteriologic study that several factors account for the respiratory flora. Transmission by air contamination can be minimized by ultraviolet radiation

with or without air conditioning. The most important contaminating agents are the fingers and the respiratory passages of human contact. Wearing face masks is only partially effective. Observance of aseptic technic is still of the utmost importance in attaining cleanliness of the hands. An important adjuvant measure is the reduction of contact between the infected and noninfected, and limitation of traffic in the nursery or sick room, for frequent handling not only contaminates the air but increases the opportunity of direct transmission from infected fingers and oral cavities. While such contact can never be completely prevented, decrease to the irreducible minimum, in conjunction with measures to lessen air infection and strict aseptic technic for hands and faces, give promise to substantially reduce the incidence of respiratory infections when, perforce, there must be congregations.

Competition for Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1945, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

Committee on Prize Essays

# THE WAR AND OXYGEN THERAPY

JOHN H. EVANS, M D, Buffalo

ONE hundred per cent oxygen therapy is a valuable aid in the treatment of many diseases and conditions which confront the medical officers of our armed forces

It can be given by inhalation, subcutaneously, and injected into joints and other cavities, such as the gastrointestinal tract, pleural sac, spinal canal, and abdominal cavity. It can also be given intravenously either as a gas or by the use of dilute hydrogen peroxide, which liberates nascent oxygen when it comes in contact with the blood. By the use of these various forms of administration it can reach pathologic processes in all parts of the body.

I shall confine this paper to inhalation and subcutaneous oxygen therapy and to their wartime uses.

Although it is well known that oxygen is essential to life and that all the vital functions are impaired in direct proportion to the degree of oxygen deficiency, the medical profession has never been greatly interested in oxygen therapy. Perhaps the chief reason for this is that oxygen has been a failure in the treatment of anoxemia. The 40 to 60 per cent oxygen, which is the dosage generally employed, fails to control anoxemia except in the milder types. When the clinician repeatedly observes that his patients are still deeply cyanotic in spite of oxygen therapy, his interest in oxygen as a therapeutic agent soon ebbs. The therapy has been considered so unimportant that its administration has been left chiefly to the fire departments, the commercial firms, and the technicians. It has come to be regarded as a therapy which is outside the realm of medical practice.

I predict that at some future date the administration of oxygen will be taken more seriously and that oxygen therapy will occupy an important place in therapeutics.

## Inhalation Oxygen Therapy

Among the wartime indications for inhalation oxygen therapy are pneumonia, shock, gas poisoning, and extensive burns. It is apparently helpful, especially when combined with positive pressure, in preventing postoperative pulmonary complications.

*Conquest of Anoxemia*—As anoxemia is usually one of the most distressing and dangerous complications of the diseases just mentioned, as

well as of other diseases and conditions, such as pulmonary edema, atelectasis, pulmonary embolism, and circulatory failure, it is most important that it be controlled. That this is not generally being done at the present time is due to the fact that oxygen is given in too weak concentrations. The reason that these weak concentrations are employed is that the oxygen tolerance of healthy animals has been substituted for oxygen dosage. Oxygen dosage for the anoxic patient is that concentration of oxygen which will restore the arterial blood oxygen to its normal level. This dosage will vary with the degree of oxygen deficiency. The oxygen tolerance of a healthy animal is the maximum concentration of oxygen which can be inhaled for a long period of time without harmful effects. As the arterial blood oxygen of a healthy animal is at its normal level, oxygen tolerance represents the percentage of oxygen which can safely be inhaled in excess of normal.

In order to calculate oxygen dosage there must be an oxygen deficiency upon which to base the dosage. No such deficiency exists in a healthy animal. The anoxic animal can safely inhale higher concentrations of oxygen than an animal whose arterial blood oxygen is at its normal level.

We have found that anoxic dogs and human beings can inhale 100 per cent oxygen without harmful effects for as long as the cause of the anoxemia exists. They can inhale that concentration of oxygen which is required to restore the arterial blood oxygen to its normal level, plus that concentration which can safely be inhaled when the blood oxygen is at its normal level.

Barach<sup>1</sup> has calculated the oxygen tolerance of healthy rabbits to be 60 per cent, which he found they could safely inhale for as long as four months.

If we assume that the oxygen tolerance of a human being is at least as great as that of a rabbit, it can be shown mathematically that a patient who has only a slight lowering of the arterial blood oxygen can safely inhale 100 per cent oxygen. In such cases 40 per cent oxygen is all that will be required to restore the arterial blood oxygen to its normal level. When this has been accomplished the patient still has an oxygen tolerance of 60 per cent. Adding the 40 and the 60, we have 100 per cent.

That continuous 100 per cent oxygen can safely be given even to patients with these mild types of anoxemia has been substantiated in a large num-

<sup>1</sup>Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10 1944.

ber of our cases. The only interruption in the treatment was for giving medicine or nourishment.

In very severe cases of anoxemia, such as exist in pneumonia when nearly all the lung tissue is involved, even 100 per cent oxygen will fail to abolish the cyanosis.

Perhaps the time will come when hospitals will be equipped with pressure chambers in which concentrations of oxygen above 100 per cent will be made available for the treatment of these cases. Until that time comes, the injection of large amounts of oxygen under the skin should be tried. In spite of the fact that there is no explanation as to why the comparatively small amount absorbed in a given time should relieve the symptoms of anoxemia, the clinical evidence is convincing. If the peripheral circulation is too much depressed the procedure may not be effective.

The objective of oxygen therapy in the treatment of anoxemia should be to restore the arterial blood oxygen to its normal level and to keep it there; as the return of anoxemia in seriously ill patients, even for a short time, may be fatal.

About five years ago two proposals for a change in oxygen dosage were made, in both of which 100 per cent oxygen was to be used part of the time. These proposals, as those for 40 to 60 per cent oxygen, are based on the tolerance of healthy animals to oxygen.

One proposal<sup>2</sup> is to give 100 per cent oxygen for the first two days and 50 to 70 per cent oxygen thereafter, and the second<sup>3</sup> is to give 100 per cent oxygen for the first two days, after which 100 per cent oxygen is to be given only half time and 60 per cent oxygen the other half.

These proposals ignore the oxygen requirements of patient suffering from severe anoxemia, in which the cyanosis will return as soon as the oxygen concentration is reduced to 50 or 70 per cent.

In 1925 I began giving continuous 80 to 100 per cent oxygen to cyanotic pneumonia patients. The report on these early cases was published in 1927.<sup>4</sup> Since then my partner, Dr. C. J. Durshodwe, and I have given continuous 100 per cent oxygen to over 800 patients who were suffering from anoxemia complicating pneumonia, cardiac failure, asthma, and other diseases. During the past several years we have reported our results from time to time.<sup>5</sup>

However, up to five years ago the use of 100 per cent oxygen was vigorously opposed by all authorities on oxygen therapy on the ground that pure oxygen was a poisonous and irritating gas, as evidenced by the fatal pneumonia it produced in healthy animals after a period of a few days. Now, some of these objectors are so enthusiastic over the good results obtained by its

use that they avoid mentioning in their reports that 100 per cent oxygen had previously been employed or advocated.

I am grateful to Barach, who is a believer in justice and fair play, for the publication of the following statement: "The proposal that very high concentrations of oxygen, 95 to 100 per cent, be used in the treatment of pneumonia and cardiac disease originated with Evans, who reported that the clinical symptoms of anoxemia were often not relieved until these high concentrations were employed."<sup>6</sup>

I recently wrote to Barach inquiring about his present views on oxygen dosage and, under date of April 20, 1944, received the following reply: "It appears to be true that your original observations on giving 100 per cent oxygen by means of a mask does not appear to be toxic to human beings over a period of two to four days. This may be because there is some interruption of oxygen treatment when the patient is fed or given fluids. In all events, I would agree that you are right in urging these high concentrations in conditions such as shock, severe hemorrhage, and any acute cardiorespiratory illness in which severe anoxia is present."

"One must remember that the Germans who were in 100 per cent oxygen in a chamber did become sick at the end of two or three days. I think it is generally true that it would be desirable to keep the oxygen concentration of the arterial blood as near normal as possible."

I am glad that Barach's present views and mine coincide on some of the important points regarding oxygen dosage. However, there are still points upon which we disagree.

Barach implies that 100 per cent oxygen has toxic effects when administered to anoxemic patients for more than two to four days. I agree that this would be the case if the patients were not anoxemic. If I interpret his statements correctly, he is of the opinion that if a given dosage of oxygen would be toxic to a healthy person, it would also be toxic to an anoxemic patient. My disagreement with him on this point is not based on theory but upon clinical observations in hundreds of cases in which 100 per cent oxygen has been given continuously for from seven to twenty-eight days. In none of the cases was there any evidence that the oxygen had toxic effect. On the other hand, there was abundant proof that the oxygen was as beneficial on the seventh, tenth, or twenty-eighth day as it was during the first two to four days.

Unlike all other therapies, in oxygen therapy the hand of the clinician is restrained before the desired results are obtained. Take, for example, insulin, which, like oxygen, is a vital constituent of the body. Although healthy rabbits have

been thrown into fatal convulsions with 10 to 12 units of insulin, the dosage in the treatment of diabetes is not limited by these figures but is determined by the degree of insulin deficiency. That the required dosage would be fatal if given to healthy individuals is of no interest whatever to the clinician.

### Positive Pressure

We have administered 100 per cent oxygen with positive pressure to over 1,400 patients. The pressure is regulated by the amount of tension placed on the expiratory valve, through which the expired oxygen escapes. The tension is increased or decreased by turning a setscrew to the end of which is attached a coil spring.

In the treatment of pulmonary edema, atelectasis, and gas poisoning the tension is increased above that ordinarily used. The spring is adjusted to produce an estimated water pressure of 4 to 6 cm. during exhalation. In severe cases of pulmonary edema this has been temporarily further increased, but not sufficiently to interfere with pulmonary circulation.

We are indebted to Barach, Martin, and Eckman<sup>7</sup> for their investigation, both by animal experimentation and clinical application, for the purpose of determining why positive pressure is beneficial in these cases. As we have used positive pressure in all but a few of our cases, it is impossible to tell how much of the beneficial results should be credited to 100 per cent oxygen and how much to positive pressure.

**Pneumonia**—The sulfa drugs, while an advance in the treatment of pneumonia, have their limitations, as they have been found ineffectual for virus and atypical pneumonia and are contraindicated for those patients who have previously acquired a sensitivity to these drugs.

Early this year the Pneumonia Advisory Committee of New York City<sup>8</sup> made the following report: "The number of reported deaths from primary pneumonia is larger than it has been for some years, and is particularly striking since it is occurring in an era when sulfonamide drugs are available. It is also high in comparison with deaths in pneumonia reported in many of the years of the presulfonamide era."

We have found that 100 per cent oxygen therapy is very beneficial in the treatment of pneumonia, regardless of the cause. The importance of employing it as early as possible even when there is no cyanosis, cannot be overemphasized. In a series of 100 cases in which oxygen therapy was begun on the first day of the disease, including various types of pneumonia, the death rate was only 6 per cent. In two of these cases continuous 100 per cent oxygen was given in spite of the fact that there was no cyanosis present at

any time. Both recovered, the pneumonia in one instance terminating in three and a half days, and in four and a half days in the second. In the other cases 100 per cent oxygen was given for from one-third to one-half of the time if there was no cyanosis, and continuously if there was.

In our report<sup>9</sup> on 409 pneumonia patients in 1935 we showed that the death rate mounted in proportion to the delay in starting oxygen therapy.

As it takes from fourteen to twenty-four hours or longer before the efficacy of the sulfa drugs can be determined, we believe that 100 per cent oxygen therapy, given for at least one-half of the time, should be started as soon as the diagnosis of pneumonia is made.

Although 100 per cent oxygen therapy in the treatment of pneumonia entails increased expense, it has the advantage over the sulfa drugs of never producing a sensitivity or any deleterious or fatal side-effects.

**Shock**—Shock, whether due to hemorrhage, anesthesia, surgical manipulations, extensive burns, or other causes, is a condition in which 100 per cent oxygen is urgently needed.

Probably the terminal cause of death in all fatal cases is anoxemia.

In shock the burden of carrying oxygen is thrown chiefly on the plasma, and when 100 per cent oxygen is given the oxygen content of the plasma is increased fivefold.

The oxygen should be administered until enough blood has been given to carry on the function of oxygenation. In shock the peripheral circulation is so greatly reduced that the deficiency of oxygen is not indicated by cyanosis. Pallor, instead, is usually present.

**Gas Poisoning**—In cases of gas poisoning the most urgent first aid treatment is 100 per cent oxygen, since the gases, especially carbon monoxide, interfere with the oxygen-absorbing power of the red cells, producing an anoxemia. The irritant gases also aid in the production of anoxemia by damaging the mucosa of the respiratory tract. More oxygen will be absorbed by the blood if positive pressure is used in these cases. The tendency is to discontinue the use of oxygen prematurely. In severe cases it should be given for twenty minutes each hour for two or three days following the initial treatment in order to prevent pulmonary complications. Sleep, however, should not be interfered with.

**Extensive Burns**—We have found 100 per cent oxygen beneficial in the treatment of extensive burns. The toxicity is reduced and the healing is enhanced.

The following is a review of our first case, which has previously been reported.<sup>10</sup>

FIG. 1. Case 1. Shows the amount of healing after several weeks' treatment by oxygen inhalation.

*Case 1.*—In 1925, a 9-year-old girl, in an outing flannel nightgown, was standing before an electric heater when her gown caught fire. More than two-thirds of her body was burned, third degree, leaving no islands of skin in the burned areas. Ten days later, when she was in a very serious condition, with temperature ranging from 101 to 105 F., and pulse rate from 120 to 150, 100 per cent oxygen was started. Her mental condition was sluggish and she took very little nourishment. Soon after the oxygen therapy was begun her mental condition returned to normal, her appetite improved, and the cyanotic color of the burned areas changed to pink. The advance of new skin began within twenty-four hours and was definitely and continuously progressive when and only when oxygen was given. The oxygen was discontinued for twelve days to ascertain whether or not the new skin would continue to grow without the oxygen. The growth of skin immediately slackened until it practically ceased. However, as soon as oxygen therapy was resumed the granulation tissue again became pink and the new skin began to advance. After seven months the entire burned area was covered with new skin. No skin grafting was necessary; however, the child was not able to straighten out her right leg because of scar tissue. The oxygen was continued, twenty minutes each hour, for another month, at which time the patient was able to straighten her leg. (See Figs. 1, 2, and 3\*.)

*Postoperative Use of Oxygen.*—We gave 100 per cent oxygen, with positive pressure, to 125 patients following major surgical procedures. Of these 78 were upper belly operations, chiefly cholecystectomies. The anesthesia was nitrous oxide-oxygen and ether. Many of these patients had either chronic or acute respiratory infections, in which it was feared postoperative pulmonary complications might develop. The oxy-

gen was given immediately after operation for from four to six hours and twenty minutes each hour thereafter for two days. There were no pulmonary complications in this series, and we believe that the oxygen was responsible for the good record, although it could be argued that the results would have been the same had no oxygen been used. We believe that the oxygen not only prevented pulmonary complications in some of the cases, but that it added to the comfort and well-being of all the patients. Coughing, which is so distressing to patients after upper belly surgery, was almost entirely absent.

### Subcutaneous Oxygen

The term "subcutaneous oxygen" is rather misleading, since it gives the impression that the oxygen stays in the subcutaneous tissue. This is true if only a small amount of oxygen is injected, but when enough is given x-rays reveal that it reaches bony structure and permeates the muscles and other intervening tissues. When given in sufficient amount around joints it apparently enters the joint cavity, as evidenced by the conversion of thick pus within the joint cavity to a thin amber-colored fluid.

The idea of injecting oxygen into or near diseased tissues is not new. Bainbridge<sup>11</sup> states that Beddoes, as early as 1799, employed oxygen for the cure of ulcers; that in 1861 Manière and Gimbernath used injections of sterilized air in the treatment of hydrocele; and that in 1861 Damarguay and his coworkers announced the cure by oxygen injection of a case of senile gangrene. Rost<sup>12</sup> in 1921 reported excellent results with subcutaneous oxygen in cases of psoas abscesses, pyemic abscesses, and infections of joints.

In 1928 Kirk<sup>13</sup> employed subcutaneous oxygen for the treatment of burns, scalds, and acute

\* Figs. 1, 2, and 3 are reprinted, with permission, from *The Medical Journal and Record*, April 4, 1928.

FIG. 2. Case 1. Shows progress as compared with a photograph of the patient taken on May 15, 1926, during six weeks of oxygen therapy.

periostitis. Many other investigators have reported favorably on the use of oxygen by this method.<sup>14</sup>

The results of my own investigation, which began in 1935, of injecting oxygen into or near the localized pathologic process has been partially reported in previous papers.<sup>16</sup>

These results coincide with those obtained by others, and apparently cover diseases and conditions not previously investigated.

It is interesting to note that in both acute and chronic inflammatory conditions the oxygen is reduced from normal. The normal oxygen pressures in healthy tissues vary between 20 and 40 mm. Hg and that of carbon dioxide between 40 and 60 mm. Hg. Campbell and Poulton<sup>16</sup> state that "in infected tissues with areas of necrosis the carbon dioxide pressure is much increased while the oxygen pressure is very low indeed, falling almost to zero." They tabulate the findings of several investigators who find that in pyopneumothorax the oxygen pressure is 0-2; in tuberculous pleurisy 0-2; in pneumothorax with exudate 0-6; and in subcutaneous cellulitis 2-3. It is apparent from these findings that oxygen

therapy is indicated in the treatment of these diseases.

Some of the wartime diseases and conditions for which subcutaneous oxygen is beneficial are local infections, arthritis in its acute stage, ringworm, burns, relief of pain following dislocations and sprains, and for promoting the healing of wounds.

The beneficial effects which result from the injection of oxygen into diseased tissues can be only partially accounted for by the correction of the local anoxemia.

For example, in acute inflammatory conditions we get relief of pain and a disappearance of local fever and redness and a reduction in the swelling and tenderness within twenty-four hours. We can only speculate as to why these results are produced. It probably works mechanically and chemically.

Mechanically it may act as follows: (1) opens up compressed lymph channels and provides better drainage; (2) serves as a buffer for inflamed tissues, thus relieving pain; (3) improves local circulation of blood.

Chemically, the excess oxygen apparently acts

FIG. 3. Case 1. Shows burns completely healed after eight months of oxygen therapy.

as follows: (1) oxidizes toxins; (2) kills the invading organisms.

**Acute Infections.**—The results obtained with subcutaneous oxygen in the treatment of acute local infections have been so uniform that they can be predicted in advance. However, I have not used it in cases of tuberculosis.

**Case 2.**—A 60-year-old steel worker had an abscess over his right knee which did not involve the joint. He was confined to bed. The knee was swollen, red, tender, and very painful. Oxygen was injected into the leg and thigh and was massaged toward the knee. Some oxygen entered the abscess cavity, as indicated by the percussion note. The pain was lessened as soon as the oxygen was injected and disappeared entirely on the following day, at which time the redness and increased local temperature had also disappeared. There was still some tenderness on pressure. At this time 20 cc. of pus were withdrawn through a needle and the oxygen was given as before. Two more such injections were given. The patient returned to work six days after the first treatment.

**Case 3.**—A resident surgeon, 28 years of age, received a stab wound between the first and second knuckles of the right hand, while assisting in a cleft-palate operation. Twenty-four hours later his hand was swollen, red, and painful, the pain extending up the arm to the axilla. He was unable to bend the middle finger and any attempt to do so caused severe pain. Oxygen was injected into the hand, forearm, and arm. The next day the redness and pain had disappeared and there was less edema. Forty-eight hours after the injection of oxygen all traces of the inflammation had vanished and full function had returned to the finger. There was some tenderness which persisted for a month. He took 1 Gm. of sulfadiazine every four hours for thirty-two hours because he was skeptical of the effect of the oxygen, which I had pictured to him in advance. Only one injection of oxygen was given.

**Case 4.**—A 76-year-old woman had a discharging abscess on the top of her head of three weeks' duration, which required daily dressings. Oxygen was injected beneath the scalp on two successive days, after which the drainage stopped.

**Cases 5, 6, and 7.**—These patients had inflamed and painful hemorrhoids, in one case of which there was a discharge of pus. In 2 cases oxygen was injected daily for three days, and for two days in the other, after which the inflammatory phase and tenderness disappeared and there was no further discharge of pus. The oxygen was not injected directly into the hemorrhoids, but into the buttock, and was massaged toward the midline. Partial relief of pain was experienced immediately in the three cases.

**Case 8.**—A 40-year-old physician was suffering from a cellulitis of both legs and feet following an x-ray burn inflicted during treatment of ringworm of the feet. The doctor suggested that only one leg and foot be injected and the other used as a control, which was done. The following day the swelling in the leg and foot which had been injected with

oxygen was reduced and the pain had disappeared. There was no change in the swelling or pain in the other leg and foot. Then the oxygen was injected into the control leg and foot and the results were the same as on the other side.

Neuritis and myositis, like other acute inflammatory infections, subside in the presence of oxygen.

**Arthritis.**—As chronic arthritis is not a subject of special interest in wartime medicine, I will report only on the acute types.

**Case 9.**—The patient was a man of 58. Two days after the start of a severe maxillary sinus infection his right hand became swollen, red, tender, and painful. For four days oxygen was injected daily into healthy areas to see if it would have any effect on the arthritis, which it did not. Then oxygen was injected into the right forearm and hand. The next day the swelling was reduced, the pain had disappeared, and there was much less tenderness. The one treatment was all that was required, although there was some tenderness when the hand was squeezed for the following ten days.

**Case 10.**—A 28-year-old woman had arthritis involving both hands and wrists and both feet and ankles. There was swelling, redness, tenderness, and pain. The arthritis was a complication of an acute follicular tonsillitis. Twenty-four hours after the first injection of oxygen the acute symptoms of the arthritis had subsided. Although another injection was given on the second day, it was probably unnecessary. There was no return of the arthritis. A tonsillectomy was done later.

**Case 11.**—A 61-year-old man had acute atrophic arthritis of the right knee, which was hot, red, and painful. It lasted two days. There was immediate relief of pain following the injection of oxygen and after four daily treatments the knee appeared normal, with full function.

**Case 12.**—The patient was a 41-year-old woman whose right hand was acutely inflamed for twenty-four hours. She had previously been successfully treated with subcutaneous oxygen for atrophic arthritis of the knees of eighteen months' duration. After one injection of oxygen the arthritis of the hand disappeared and has not returned.

**Burns.**—While our experience with subcutaneous oxygen in the treatment of burns is somewhat limited, it seems that the growth of new skin advances much more rapidly when oxygen is injected into the burned and adjacent areas. In one case of severe burns subcutaneous oxygen was combined with inhalation oxygen with gratifying results.

As oxygen apparently has the effect of neutralizing toxins, I believe it possible that, if oxygen were injected immediately into burned areas, constitutional effects might be lessened or aborted. I cite the following experiment, merely for the purpose of stimulating further investigation, and not with the idea that the re-

sults obtained are significant. They are only suggestive, and may or may not be duplicated in further experiments. Two large white rabbits of the same litter that were kept in the same cage were anesthetized and the skin over the abdomen was burned with a hot iron. Under the burned area of one rabbit a layer of oxygen was maintained for a period of six weeks, the injections being given every other day. This rabbit, although its burn happened to be more extensive than that which was inflicted on the other rabbit, did not at any time appear sick, there was no loss of appetite, and there was a progressive increase in weight. No oxygen was injected into the other rabbit. The following day it began to appear sick, the eyes looked dull, and the appetite began to fail. During the following six weeks there was a progressive loss of weight until there was barely skin and bones left.

**Wounds.**—I am convinced that subcutaneous oxygen hastens the healing of open wounds. My observations have been that it keeps the wound more sterile, lessens the discharge, and improves the blood supply. In order to prove that my deductions are correct, exacting animal experimentation would be necessary.

Perhaps the most convincing clinical evidence I can offer is the healing of long-standing varicose ulcers of the leg by the injection of oxygen. The following is a report of one of our cases:

**Case 13.**—A 35-year-old pharmacist, who was on his feet almost every day for twelve hours, had a varicose ulcer on each leg, the size of a half a dollar, of two years' duration. Subcutaneous oxygen was given three times weekly for six weeks, at which time the ulcers were healed. He did not stop work during the treatment. After the first few treatments the odor, which had been quite marked, disappeared and the discharge gradually lessened.

**Ringworm.**—I understand that many people in our armed forces are suffering from ringworm of the severe type. My experience in the treatment of this disease may be of interest. I do not claim that oxygen therapy is a cure, but from my observations it is a great help in clearing up bloody discharge and in healing of ulcerations. The results have been uniform in the few cases treated.

**Case 14.**—A girl, 16 years old, had ringworm involving the right foot of six months' duration, which was getting worse in spite of the usual remedies. There was a bloody discharge between the toes. After the first few injections of oxygen and the bloody discharge stopped after the third. The small ulcer healed after the first few injections and the one on the sole of the foot after six weeks.

The injections were given twice weekly.

**Dislocations and Sprains.**—Subcutaneous oxygen not only relieves pain following dislocations and sprains but apparently hastens the restoration of injured tissues to their normal state.

**Case 15.**—A 45-year-old man sustained dislocation of his right hip, which was reduced. A week later he found walking, which he did with the aid of a cane, very painful. Immediately after the injection of oxygen into the right buttock and thigh the pain was so much relieved that he could walk without the aid of the cane. He reported the next day and said that no more treatment was necessary, as the hip was back to normal.

**Cases 16, 17, 18, and 19.**—Four patients with sprained ankles were treated. The sprains had taken place several days before subcutaneous oxygen was given. Walking was still painful and there was some edema. The pain and swelling in all cases disappeared after one injection of oxygen.

**Case 20.**—A 60-year-old woman had a severe sprain of the right ankle with marked swelling due to hemorrhage. Oxygen was injected an hour after the accident, with partial relief of pain. Three more treatments were given during the following week, after which the pain and swelling disappeared.

**Case 21.**—A 72-year-old woman was seen two days after a severe sprain of the right knee, which was swollen and painful. Immediately after the first injection of oxygen she was able to walk and there was very little pain. After a week, following two more treatments, her knee returned to normal.

#### Suggestions for Subcutaneous Oxygen Research

To those who may be interested in research and wartime medicine, I suggest that the possibilities of subcutaneous oxygen be investigated in the following diseases and conditions, which are practically virgin fields:

1. To prevent infection when foreign objects, such as bullets or pieces of shell penetrate deeply into the tissues.

2. To inject into the area of penetrating wounds to prevent tetanus in patients who are sensitive to horse serum.

3. To relax spastic muscles following cord or other injuries. This suggestion is based on the use of subcutaneous oxygen in three cases of poliomyelitis. In two there was spasticity of the neck muscles, which disappeared after the first injection of oxygen. The third patient was a 9-year-old girl with spasm of the muscles of the right thigh, because of which she was unable to straighten her leg. Immediately after the injection of oxygen the spasm disappeared and she could straighten her leg. I called her family physician a month later and he said the spasm had not returned.

4. To prevent atrophy of muscles and nerves when it is necessary to immobilize any part of the body for long periods of time.

5. To determine the viability of the circu-

lation in cases of crushing injuries. This suggestion is based on the good results obtained in circulatory disease of the extremities when amputation was threatened on account of beginning gangrene, and also on the verbal report of a friend of mine who was called to give an anesthetic for the amputation of a crushed finger. The surgeon consented to wait until subcutaneous oxygen had been tried. The result was that the finger healed and amputation was found unnecessary.

6. For the prevention and treatment of sepsis in compound fractures.

7. For pleurisy, with or without effusion, and for empyema.

8. For the prevention and treatment of pressure sores.

### Suggestion for Inhalation Oxygen Research

The inhalation of 100 per cent oxygen for the treatment of seasickness.

I have successfully treated three cases, the first in 1925 on Lake Superior. Two other cases were treated, but I did not observe them, as I only furnished the apparatus. The report was "no effect."

### Conclusions

The inhalation of 100 per cent oxygen is beneficial in the treatment of: (1) anoxemia; (2) pneumonia; (3) shock; (4) gas poisoning; (5) extensive burns; and (6) as a probable aid, combined with positive pressure, in preventing postoperative pulmonary complications.

The injection of oxygen subcutaneously is an aid in the treatment of (1) acute local infections, in which cases the results are often spectacular; (2) the acute phase of arthritis; (3) ringworm complicated by ulceration; and (4) burns.

### Discussion

Dr. Alvan L. Barach, *New York City*.—For many years Dr. Evans has advocated the inhalation of 100 per cent oxygen and has consistently reported no ill effects from its use. It does now appear, on the basis of many subsequent reports (Boothby, Mayo, and Lovelace, Fine) that these high concentrations of oxygen may be inhaled by human beings for two and probably for as long as four days when given by mask. Perhaps one of the reasons that 100 per cent oxygen can be tolerated for periods as long as these in human beings is that mask administration of oxygen is accompanied by interruption of oxygen treatment from time to time when the patients are given fluids or food or have their faces cleaned. Interruption of oxygen treatment seems to delay and to some extent to prevent the injurious effects of inhalation of high concentrations of oxygen which have been so consistently observed in animals who have lived continuously in chambers. However, the experience of Clamann and Becker-Freyseng indicated that they became ill at the end of two days in 90 per cent oxygen in a chamber and on the third day suffered from unmistakable lassitude, slight fever, and signs of congestion in the lungs in one of them.

Inhalation of a concentration of 95–100 per cent oxygen would appear to be of especial value in cases of coronary occlusion, shock, hemorrhage, and, in fact, any very severe clinical condition characterized by marked anoxia. However, a caution must be inserted at this point as to the employment of mask oxygen therapy. In a number of instances the patient will tolerate the mask applied to his face for short periods only. When this is the case oxygen therapy by mask should be discontinued, since intermittent oxygen therapy has only a limited field of usefulness. In patients with pneumonia, asthma, and heart failure continuous oxygen therapy is generally indicated.

If the patient cannot tolerate with comfort the constant application of the mask to his face, oxygen should be given either by a well-ventilated and well-administered tent or by a catheter placed in the oropharynx.

I wish to say a few words concerning the indication for the use of positive-pressure respiration. We first employed the inhalation of a therapeutic gas under an increased pressure of 4 to 6 cm. of water, occasionally as high as 10 cm., in the treatment of obstructive dyspnea, in conjunction with helium-oxygen therapy. In patients with asthma or obstructive lesions in the trachea and pharynx, an increased negative pressure during the inspiratory cycle is generally present within the lungs and in the

intrapleural space, which is necessary to draw air in past the point of constriction. It is this negative pressure within the lungs that appears to be responsible for many of the dangerous consequences of obstructive dyspnea. The inhalation of a therapeutic gas under a positive pressure during inspiration has the advantage of gently pushing the inhaled atmosphere into the lungs and in that way lessening the pathologically elevated negative intrapulmonary pressure. During expiration the bronchi do not constrict as much when breathing is conducted under positive pressure. Poulton employed positive pressure in the treatment of proxymal cardiac dyspnea, with improvement in some cases, and also noted improvement in a few cases of bronchial asthma, although he utilized this procedure for very brief periods only.

We have also used positive pressure at Presbyterian Hospital in the treatment of pulmonary edema, and in many instances in which this complication took place in the course of pneumonia, observed a clearing of the signs of edema. Positive pressure, when administered for the treatment of obstructive dyspnea, must be given during both phases of the respiratory cycle. In the treatment of acute pulmonary edema it is also more effective to employ it during both inspiration and expiration, but the clearing of edema has been accomplished in some instances by breathing against a positive pressure during expiration only. Pressures of 4 to 6 cm of water may be employed, although the latter pressure, when used during the expiratory cycle only, does cause discomfort and can be employed for only relatively short periods. This pressure in expiration may be obtained by exhaling through a tube placed under the appropriate water level or by exhaling through a disk with various-sized constricted orifices.

An exceedingly interesting case of irritant pulmonary edema caused by the inhalation of an irritant gas was observed by Dr. Rovenstein, who was kind enough to send me the notes on this case for publication.

The improvement seemed to be specifically related to the inhalation of oxygen under positive pressure during expiration.

The only contraindication that may be present to the inhalation under positive pressure is that of shock. When there is a difficulty in the return of blood to the right side of the heart, the increased

intrapulmonary pressure which takes place during positive pressure respiration may further retard the entrance of blood into the auricle. However, it might be that positive pressure in expiration only may have a therapeutic value in clearing the edema of the lungs that takes place not uncommonly in cases of shock and the application of pressure during only one phase of breathing may not seriously interfere with the circulation. When positive pressure is tried in the treatment of edema of the lungs during peripheral circulatory failure, the pathologic physiology of the clinical entity should be kept in mind and the pressure given cautiously, with frequent determinations of the systolic blood pressure.

The use of oxygen subcutaneously would not appear to exercise a therapeutic effect by increasing the saturation of oxygen in the arterial blood. The mechanical influence of introducing oxygen under the skin may be of very considerable value, as Dr. Evans has indicated, in the treatment of sprains and in those conditions in which spasm of muscles is present. In all events, the favorable results which we have heard this afternoon would suggest further trial of this procedure in the various clinical entities described.

**Dr. John H. Evans**—The discussion by the various members reveals the fact that the healthy animal is still being used in the determination of oxygen dosage for the anoxic patient. Dr. Barach has stated in reply to inquiries that he has never used anoxic animals for his oxygen experiments, also that the Germans who became ill at the end of two days in 90 per cent oxygen in a chamber were healthy when they entered the chamber. In my opinion, whenever an investigator reports that a given percentage of oxygen produced harmful effects, he should make it clear to the reader whether or not the person or animal was suffering from anoxemia before the experiment began. For example, when the term "experimental animal" is used the reader is still in the dark on this point.

Please bear in mind that no one has ever shown that the continuous administration of 100 per cent oxygen is harmful to a human being or animal suffering from anoxemia. We have proved in hundreds of cases that continuous 100 per cent oxygen is not only harmless but exceedingly beneficial when given to anoxic patients for as many days as there is indication for oxygen therapy.

#### REQUESTS FOR BIOGRAPHIC SKETCHES

The success of established publications such as *Who's Who in America*, *The American Medical Directory* published by the American Medical Association, and *The Directory of Medical Specialists*, compiled by the Advisory Board for Medical Specialists, has apparently led others to believe that this is a field worthy of commercial exploitation.

It is presumed that the financial success of such

publications may depend in large part upon the sales of the volume itself. But the sales record of an individual publication might better depend on its intrinsic value as a source of reference for accurate and perhaps specialized information. It is suggested that those solicited may well consider this fact in determining whether the information desired should be supplied.—C. H. C., in *Wisconsin M. J.*, Aug 1944.

# PENETRATION OF ALLERGENS INTO THE HUMAN SKIN\*

FRANZ HERRMANN, M.D., New York City, MARION B. SULZBERGER, Comdr., (MC), USNR, and RUDOLF L. BAER, M.D., New York City

## I. Skin Penetration by Allergens Coming from Without—with Remarks on Contact Urticaria and Contact Atopic Dermatitis, Including "Infantile Eczema"

In order to elicit skin reactions, substances coming from without must first penetrate the natural barriers of the skin's surface. Allergens of contact-type eczematous dermatitis, either during clinical exposures or when applied as patch and other tests, may be assumed to reach at least the living epidermal cells. Similarly, penetration through the outer skin barriers must be assumed in the case of allergens in feathers, wool, silk, in human and other animal danders, etc., in tuberculin, trichophyton, etc., whenever these produce allergic reactions after exogenous contact with the skin's surface, either in the course of natural exposures in such diseases as atopic dermatitis, "infantile eczema," or urticaria, or when applied in the form of skin tests.

There are not a few reports of the transepidermal penetration of even the ordinary wheal- and flare-producing allergens. This phenomenon has previously been discussed at some length by Peck and Salomon,<sup>1</sup> Sulzberger,<sup>2,3</sup> Osborne and Walker,<sup>4</sup> M. Albert and M. Walzer,<sup>5</sup> and other authors. Artificial conditions, such as the rather vigorous and prolonged inunctions of allergens suspended in petrolatum practiced by A. Walzer,<sup>6</sup> quite regularly succeed in driving allergens through the probably somewhat abraded skin. The reports of Abramson and Engel<sup>7</sup> are somewhat more pertinent, for they describe the spontaneous transepidermal passage of wheal-producing allergens in certain of their subjects.

Perhaps the description of some of the cases which have come under our own observation may illustrate this phenomenon. As already mentioned,<sup>2,3</sup> we have seen a series of patients in whom the application of "protein" allergens by classic scratch tests elicited urticarial reactions, not only at and around the site of the scratch, but whenever and wherever the allergen-containing fluid touched the grossly unbroken

skin's surface. Thus, where the silk-allergen-containing fluid or the egg or wheat or other allergen solution happened to run down the back or arm from the site of the scratch test, wheal and flare reactions appeared along the entire course of the droplet's contact with the skin. However, even in these cases the transepidermal penetration was not a general one which included all the allergens to which the patient reacted on scratch test, but was in each case apparently selective and limited to certain of these allergens.

In addition to these reactions observed during skin tests, we have seen not a few clinical manifestations proving the penetration of urticariogenic allergens across the skin barriers. These cases may be called "contact urticaria" or "contact atopic dermatitis," etc.

*Case 1.*—A. L., a 5-year-old girl who had been under our care for infantile eczema and atopic dermatitis, while waiting in the office on a warm summer's day, snuggled up against her mother. The mother was wearing a silk blouse. In a few minutes urticarial reactions appeared on one side of the child's face, neck, and shoulder. The discrete wheals were disseminated over and confined to those sites which had been in close contact with the mother's silk garment. At another time this same patient sat on a silk scarf while waiting her turn, and the hives appeared over the appropriate regions. The scratch skin tests with silk were strongly positive in this case.

*Case 2.*—The case of Mrs. H. S. was similar to that of A. L. Here the wearing of certain types of woolen sweaters produced severe itching and discrete wheals at the sites of direct contact and was followed by exacerbations of the patient's atopic dermatitis. In this patient our skin test consisted of cutting out a small piece of the offending sweater, moistening it with water, and merely laying it on a grossly unaffected skin site. Within a few minutes this application produced a cluster of wheals confined to the square of contact and also elicited a crisis of fairly generalized itching.

However, it is noteworthy that by no means all silk or wool garments or tissues produced transepidermal reactions even in these two patients. A. L.'s mother could demonstrate that only *certain* of her silk clothes produced hives through contact with the child's skin, and Mrs. H. S. was able to discover the few among her woolen clothes which elicited her hives and itching. Nor would the "contact whealing" take place at each and every exposure to the offending garments.

*Case 3.*—Another instructive instance was observed in a barman whose hands swelled and itched within a few minutes after contact with orange and

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944.

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University (Dr. George M. MacKee, Director); under a research grant of Wallace Laboratories, Inc., New Brunswick, New Jersey.

\* The opinions and assertions contained in this article are the private ones of the writers and are not to be construed as official or reflecting the views of the Navy Department or the Naval Service at large.

grapefruit, and whose perioral regions erupted with swelling and itching when orange juice was drunk.

There were among our patients also several bakers, whose hands immediately itched and ballooned forth on contact with wheat flour, and 2 patients who responded with urticarial reactions to carrots as soon as these vegetables touched their skin. We have seen similar immediate urticarial responses to external contacts with other agents, including egg-white and fish.

It is to be particularly emphasized that none of these clinical reactions were of contact-type *eczematous dermatitis*. In some of these cases secondary *eczematization* was present, but the primary reaction was always one of edema, erythema, and itching *beginning within a few minutes after exposure*. It is of great significance to note that none of these patients reacted with typical *eczematous* twenty-four- to forty-eight-hour responses to classic patch tests with the allergens concerned; they did, however, react with unequivocal, immediate wheal reactions to the orthodox scratch tests with the particular allergens.

Still other examples of "protein" allergens penetrating from without are the not uncommon cases of *eczema* of the face and scalp in infants, in which the allergenic contents of feather or kapok pillows or mattresses, wool blankets, clothes, etc., are the culprits and produce local reactions at sites of contact. Our clinical observations indicate that in adults the eyelid areas, the hands, the feet, the perioral and perianal and genital areas seem to be particularly prone to contact-urticarial responses. Urticarial and edematous reactions of the genitalia produced by contact with certain finishes in clothing are, of course, well known.<sup>8</sup> Moreover, as one of us has frequently stressed, many infants and young children and perhaps also many patients with atopic dermatitis seem to have less adequate protective skin barriers than have normal adults. In addition, certain factors, particularly sweating, the slightest friction, the most superficial alkali damage, often seem to promote the penetration of substances coming from without.

*Case 4.*—We could cite numerous other cases in which urticariogenic allergens penetrated to the cutaneous vessels. Thus, the skin of a nurse in a syphilis clinic responded with typical local whealing within a few minutes after droplets of therapeutic arsphenamine or neoarsphenamine solutions touched its surface. In this patient a tremendous local wheal encompassing the whole forearm and part of the upper arm followed our skin test, which consisted of a droplet of dilute neoarsphenamine solution applied to grossly normal skin; and the local response was accompanied by a severe constitutional reaction and an asthmatic attack.

Despite these many examples of urticarial responses to external contacts ("contact urticarias"), these cases nevertheless represent the *exceptions*. The rule is that the so-called "protein" allergens which are the common causes of urticarial responses are unable to penetrate through the intact surface of the human skin with sufficient speed and in sufficient quantity to produce grossly visible whealing. Because of this usual high degree of impermeability of the skin to urticariogenic allergens, skin testing for the urticarial reactions of allergy necessitates the employment of technics which will facilitate the access of the allergen to the vascular layers of the cutis. For this purpose the patch test, inunction test, or other tests consisting of mere external applications are not generally adequate; and the orthodox scratch test, or other abrasive or scarification test, or the intracutaneous test technics are employed to sever or pierce the protective skin barriers and bring about the desired contact between the allergen and the vascular shock tissue. All of these technics involve certain difficulties—e.g., some (slight) danger of infection, risk of inadvertent mixture and reciprocal contamination of allergens, and, particularly in children, varying degrees of emotional and psychic trauma.

The augmentation of skin penetration which was achieved by using certain new composite vehicles<sup>9</sup> in our earlier studies with sulfonamides, mercurials, etc., prompted us to study the possible effects of such vehicles on the transepidermal penetration of urticariogenic allergens.

## II. Experimental Studies with New Penetrating Vehicles

*A. Clinical Material.*—Our studies on the efficacy of inunction tests with protein allergens mixed with the composite vehicles were carried out on a group of 51 patients suffering from atopic dermatitis and on 3 normal adults whose skin sites were passively sensitized by the Prausnitz-Kustner technic.

In all the atopic cases the skin had previously been shown to respond with an urticarial reaction to scratch tests with one or several protein allergens.

The subjects included male and female patients whose ages ranged from 2 to 67 years.

*B. Procedure and Technics.*—In the atopic subjects all skin tests were carried out on clinically normal and intact-appearing skin sites at some distance from skin areas which were involved by the atopic dermatitis. A drop of the selected vehicle was placed on the chosen skin site by means of a medicine dropper. A small amount of powdered protein allergen was picked up with the flat end of a toothpick and deposited on top of the drop. The rounded end of a glass

rod, 4 to 6 mm. in diameter, was then used to mix the vehicle and powdered allergen; and by gentle but thorough rubbing into the skin the resulting mixture was distributed over an area about 2 to 3 cm. in diameter. The inunction was carried out for a minimum of ten seconds and in the large majority of tests for thirty seconds.

*C. Allergens Employed.*—The allergens used included the following:

1. Foods: Egg (white and yolk), milk, casein, veal, pork, lamb, bluefish, herring, sole, halibut, codfish, lima bean, navy bean, peas, carrots, tomatoes, spinach, wheat, corn, rye, oats, grapes, lemon, oranges, apple, grapefruit, peach, strawberries, pineapple, peanut, cocoa, coffee.

2. Pollens, Epidermals, etc.: Short ragweed, giant ragweed, cocklebur, march elder, orchard grass, blue grass, june grass, timothy, red top, rose, hemlock, hickory, sycamore, white oak, locust, orris root, pyrethrum, tobacco, cotton, cat hair, goat hair, horse dander, horse hair, goose feathers, chicken feathers, dust, silk, kapok.

*D. Objectives, Tests, and Controls.*—In these studies we had four principal objectives in view:

1. To observe whether the new composite vehicles actually achieved a significant increase in the penetration of the allergen into the unbroken skin as compared with the allergen alone or with the allergen suspended in the vehicle commonly used for dissolving powdered allergens in scratch tests (N/10 sodium hydroxide).

2. To observe the degree to which the various constituents of the different vehicles each contributed to any increase in penetration achieved by the respective complete vehicle.

3. To compare the reactions elicited by inunction of the allergen plus the complete vehicles with the reactions produced by the same allergen applied by the orthodox scratch-test technic.

4. To rule out nonspecific irritative and traumatic effects of both the scratch and the inunction tests.

To accomplish these four purposes, in each subject each allergen was applied in a series of tests, as shown in Table 1.

*E. Vehicles Studied.*—In the 51 subjects, a total of 584 such complete series of tests have been carried out with the following four vehicles, their constituents, and the above described controls:

Vehicle A	Aerosol MA	1 weight part
	antipyrine	1 weight part
	xylene	1 volume part
	propylene glycol	4 volume parts
Vehicle B	Aerosol IB	1 weight part
	antipyrine	1 weight part
	xylene	1 volume part
	propylene glycol	4 volume parts

Vehicle C	Sodium p-xylene sul- fonate	1 weight part
	antipyrine	1 weight part
	propylene glycol	5 volume parts
Vehicle D or analogous combinations	Alkyl benzene sul- fonate mixture	2 weight parts
	antipyrine	2 weight parts
	water	2 volume parts
	propylene glycol	5 volume parts

It is obvious from the above-mentioned figures of 584 complete series of tests that many of the 51 patients were tested, not only once and not only with one allergen, but repeatedly and with several allergens. Some were tested twice weekly for periods of time ranging up to twenty-eight months.

*F. Results and Discussion.*—1. Description of Reactions: In general it may be said that the inunction tests with the penetrating vehicles frequently produced urticarial reactions of considerable intensity (Fig. 1). As a rule, the reactions appeared within two to five minutes after inunction, sometimes even earlier, and in some cases before termination of the inunction procedure. The reactions manifested themselves first by erythema accompanied by a slight diffuse elevation and followed by the formation of minute wheals at or around the openings of the hair follicles. In the stronger reactions, as these discrete wheals became larger they coalesced and eventually formed one large wheal with pseudopods and surrounded by more or less marked erythema. The reaction then gradually subsided, passing through a stage during which the erythema surrounding the wheal disappeared, while the area previously covered by the wheal became erythematous and slightly edematous.

TABLE 1

- |    |  |
|----|--|
| A. | Inunction tests with respective powdered allergen with at least one, but usually with several of the complete vehicles.  |
| B. | Inunction tests with vehicles alone (to rule out the urticariogenic or irritating effects of the vehicles themselves).   |
| C. | Inunction tests with powdered allergen and with each separate constituent of the vehicles, as well as with incomplete combinations of constituents of the vehicles (to observe the action of individual components and combinations of components).  |
| D. | Inunction tests with separate constituents alone or in different combinations and without the presence of allergen (to rule out the urticariogenic or irritating effects of the constituents themselves).  |
| E. | Control inunctions of the powdered allergen alone; and of the powdered allergen plus N/10 sodium hydroxide (to ascertain the penetrating capacity of the allergen alone; and of the allergen in the most commonly employed vehicle).   |
| F. | Control scratch tests with powdered allergen plus N/10 sodium hydroxide; and with N/10 sodium hydroxide alone (to ascertain the subject's response to the allergen in the usual form of testing, and his response to the trauma and chemical effects of this test in the absence of allergen). |

FIG 1 Reactions to inunction tests in patient strongly positive to scratch tests with kapok

- 4 Inunction of kapok plus 1/10 N sodium hydroxide

(Photo about 25 minutes after application of tests)

2 False Negatives Taking the *scratch test results as an absolute standard*, the various vehicles and components gave the incidence of "false negatives" shown in Table 2 ("False negative" signifies that the results of the inunction of the powdered allergen with the particular vehicle were negative, while the scratch tests were positive.)

As far as the inunctions in the *absence of allergens* are concerned, the control inunctions with the vehicles, with the separate constituents, and with combinations of constituents, did not produce whealing except in a few individuals who were shown to have dermatographism. These traumatic or dermatographic reactions were much more transitory than true allergic whealing and did not resemble the allergic urticarial reactions to a sufficient degree to confuse the results. As a matter of fact, it was our impression that the difference between traumatic dermatographism and allergic urticarial reactions tended to be rather more distinct with inunction tests than with intradermal or scratch tests.

TABLE 2—FALSE NEGATIVES

With propylene glycol	67	per cent false negatives
With propylene glycol plus antipyrine	65	per cent false negatives
With propylene glycol plus antipyrine plus xylene	62	per cent false negatives
With N/10 sodium hydroxide	52	per cent false negatives
With propylene glycol plus aerosol MA		
Similarly with propylene glycol plus aerosol IB and with propylene glycol plus Na p xylene sulfonate	(average)	12.7 per cent false negatives
With propylene glycol plus antipyrine plus aerosol MA		
Similarly with propylene glycol plus antipyrine plus aerosol IB	(average)	7.6 per cent false negatives
With complete vehicle C	4	per cent false negatives
With complete vehicle A	2	per cent false negatives
With complete vehicle B	2	per cent false negatives
With complete vehicle D	0	per cent false negatives

As will be seen in Table 2, the incidence of false negatives decreased as the various constituents of the vehicles were added, and reached an absolute minimum—that is, zero—with the complete vehicle D. It should also be mentioned that the reactions with the allergen plus *complete* vehicles, and particularly plus complete vehicle D, tended not only to be more regular but also on the whole to be stronger than those elicited by the allergens plus separate constituents, or by allergens plus incomplete combinations of constituents.

3 Selective Increased Penetration of Different Allergens Since, in contrast to vehicles A, B, and C, the inunction tests with the allergen powders in type D vehicle produced a positive result in every instance in which the scratch test was positive, it may be concluded that type D vehicles are, in this respect, the most efficient we have developed to date. However, the type D vehicles were developed only after trials and experiments lasting over one and a half years. Our earlier vehicles, A, B, and C, were all characterized by the fact that they contained xylene or its derivative p-xylene sulfonate. These vehicles, when considered separately, failed to produce a satisfactory minimum of false negatives. However, in their aggregate and when a positive reaction with any one of the three was considered as significant, the false negatives went down to 0.25 per cent. This fact is best explained by our observation that certain allergens can be made to penetrate best by the use of distinctly lipophilic carriers, as represented by vehicles A and B, while other allergens penetrate best with hydrophilic agents, such as vehicle C. On this basis the allergens we used could be divided roughly into two large groups. All foods and all pollens, except those of the white oak and locust, penetrated better with vehicles A and B, while all "inhalants" except pollens, and all "epidermals," with the notable exceptions of silk and kapok, penetrated better with the more hydrophilic vehicle C.

Our search for a vehicle that would prove to be

a "universal carrier" for all allergens led to the development of type D vehicles. And, as shown in Table 2, this type of vehicle appears to have the desired property of carrying all categories of allergens into the skin with equal facility. Moreover, since type D vehicles contain no xylene or derivatives, they are even less likely to irritate the skin than the xylene-containing combinations. We have been able to apply type D vehicles even to some of the most sensitive skin areas, and we have indications that they may be used with impunity even on mucous membranes.

4. False Positives: Up to this point our discussion has mentioned the discrepancy in only one direction—i.e., when the inunction tests were negative but the scratch tests positive. A few words must be said about the discrepancy in the opposite direction—i.e., about *positive* inunction tests in the presence of *negative* scratch tests. These false positives with the inunctions could often be accounted for on a purely quantitative basis—by the observation that the inunction tests were, on the whole, "stronger" than the corresponding scratch tests. There were, for example, several instances in which the inunction tests were positive, the intracutaneous tests were also positive, but the scratch tests were negative. Moreover, when, during the course of repeated inunction and scratch tests, the patient's skins tended to manifest a diminution of sensitivity, the scratch test reactions would frequently diminish in intensity and even fail to appear at a time when inunction tests still elicited strong reactions.

### III. Conclusions and Remarks

In conclusion, our results appear to warrant the following statements:

1. Type D vehicles—i.e., the most recently developed, xylene-free combinations—are relatively nonirritating solutions which greatly promote the transepidermal penetration of all the powdered "protein" allergens we employed.

2. The results obtained in our inunction tests with these vehicles correspond closely with those obtained in the same cases with the orthodox scratch test.

Despite this close correspondence, we do not believe that our results prove that our inunction tests with the new vehicles can, in the present state of our knowledge, supplant the orthodox scratch or intracutaneous technics. On the contrary, it must be emphasized that the decision as to the practical value of the new vehicles and tests must await the results of further studies. Our present experiments were carried out almost exclusively in patients with atopic dermatitis who, as previously stated, are inclined to have skins of less than normal impermeability. We

have, as yet, insufficient information on how reliable the inunction tests will be in normals or in patients with such conditions as urticaria, asthma, hay fever, etc.

Another of the many problems requiring further study is that of the possible use of inunctions with the new vehicles as means of administering allergens for specific *prophylaxis and desensitization* therapy. While there is some evidence that intra- or percutaneous administration of antigens and allergens is often a particularly effective route, and while there are certain factors which would seem to support the possible usefulness of inunction versus subcutaneous injection, large series of further studies will be needed to demonstrate the clinical effects of percutaneous inunctions in the new vehicles.

### Discussion

Dr. Mary Hewitt Loveless,\* *New York City*—Whereas Drs. Sulzberger, Baer, and Herrmann have done pilot experiments with numerous vehicles and many allergens, we have restricted our studies to one allergen—pollen—and to two vehicles. One of the latter was lipophilic (type A), and the other was a universal carrier referred to as type D by Dr. Sulzberger. Our aim was to learn whether these vehicles would carry sufficient allergen through the intact skin to be of use (a) in the diagnosis and (b) in the treatment of pollen hay fever.

Our clinical material consisted of 52 patients with clinically proved pollen-allergy (usually ragweed hay fever or asthma). The degree of sensitiveness ranged from slight to extreme. Approximately half the group never had been tested or treated before consulting us and receiving inunction tests. With a few exceptions, only one set of tests was performed on each individual, so that all tests would be comparable.

The materials to be tested were gently rubbed onto the skin of the forearm with a large, smoothly rounded glass rod for exactly two minutes. The test materials were as follows: (1) crude, undefatted

\* From the New York Hospital and Department of Medicine, Cornell University Medical College, New York City.

pollen wetted with vehicle A, (2) crude, undefatted pollen wetted with vehicle D, (3) crude pollen moistened with buffered saline solution at pH 7.4, (4) vehicle A alone, (5) vehicle D alone, and (6) buffered saline solution alone. The first dozen tests with the last three of these gave uniformly negative responses and were subsequently omitted. The other injections were capable of producing in suitable patients small wheals of about 1 mm diameter surrounded by erythema which reached a maximum in twenty to thirty minutes. Sometimes the wheals were so numerous that they became confluent.

Concurrently with the injection tests, we performed threshold tests of the conjunctiva of the skin (intracutaneous technique) and, in the instance of 21 previously untreated cases, of the nasal mucosa. Blood samples were also withdrawn so that the serum antibodies could be studied. At the termination of the testing period comparisons were made between the results with the new vehicles and the older testing methods to gauge the efficiency of the injection technique. Ten patients took daily injections to test the therapeutic effect of giving antigen through the intact skin.

**Findings**—As a preliminary step, the relative effectiveness of the two vehicles as carriers of pollen was investigated. Some patients reacted more with one vehicle than with the other but the differences were not marked and were about equally distributed between the two solutions tested. To simplify our analysis, we selected the larger of the reactions for each patient as representing his response.

Among 52 hay fever cases, 30 gave wheal-and-flare reactions to pollen mixed with one or each of the vehicles, the degree ranging from slight to very marked. This means that there were 42 per cent of false negative reactions among our proved cases of pollen sensitiveness. All 52 subjects gave definite responses to the concurrent tests of the eye, skin, nose, and serum.

When comparison was made between the injection test and the conjunctival test in these patients, it was apparent that a greater incidence of marked conjunctival sensitivity existed among those who showed positive reactions to injection than among those with negative injection tests. Similarly, patients giving positive injection responses tended to show greater reactivity to intracutaneous test than did those who failed to react percutaneously. This was also true for the nasal test.

We were surprised to find that about half of the positive reactors to injection tests with penetrants also responded, although to a lesser degree, to injection with buffered saline solution and pollen. The new vehicles seemed only to enhance an already existing tendency for pollen to penetrate the intact skin under the influence of gentle rubbing. Although the tendency for the injection to produce positive responses was in general greater as the intracutaneous, ophthalmic, and nasal sensitivity of the patient was more marked, there were notable exceptions to this relationship. Injection reactions failed to appear in occasional cases of high sensitivity, indicating that special skin barriers, such as an oily coating, may have been present in these individuals.

Following their tests, the majority of the patients were given specific subcutaneous injections. It is our custom to augment the dosage as rapidly as possible, the rate varying with the individual. It was found that those patients who gave decided reactions to the injection tests were, in general, less able to tolerate rapid dosage increases than the nonreactors. Furthermore, generalized responses to injection occurred five times more often in the positive injection test group than in the negative group.

These observations relative to therapy lead us, as did the preceding tests for sensitivity, to conclude that highly allergic patients are the ones who usually respond to injection tests. Since markedly allergic subjects are also more responsive to scratch test than are the relatively insensitive patients on the whole, it is probable that the low incidence of false negative reactions found by Dr. Sulzberger and co-workers with the injection test is attributable to the fact that he used the positive scratch reaction as the basis for comparison. Moreover, as is well known, atopic dermatitis patients such as were employed by Sulzberger and his collaborators represent a particularly highly skin-sensitive group.

Ten patients who had given marked responses to injection test were instructed to take daily rubs at home as a form of therapy. They began with a dose of one toothpick pointful of crude pollen, rubbing it gently into the skin of the arms or legs for ten minutes with vehicle A (or D) each evening. The dose was increased as rapidly as possible, the localized reactions serving as an index to the tolerance. Treatment was continued for from six days to three months and the top daily dose ranged from one toothpick pointful of pollen to seventeen. Localized urticarial reactions occurred promptly after all injections, and untoward responses were experienced by all but one subject. The latter developed after two or more injection treatments, appeared within twenty minutes to twelve hours after the rub, and persisted for from one to twenty-one days after therapy was discontinued. There were six instances of hay fever in different patients, seven cases of dermatitis, and one attack of asthma, all probably related to injection. The eruption was maculopapular, intensely pruritic, and lasted for four days to three weeks, although therapy was discontinued as soon as the rash appeared. It was in no instance vesicular and, in the opinion of Drs. Sulzberger and Baer, resembled an atopic dermatitis caused by external contact rather than a contact type of eczematous dermatitis. The idea that pollen antigen may have passed percutaneously into the general circulation was strengthened by the complaint that previous and distant sites of injection as well as the skin generally, became very itchy some twenty minutes after injection treatments. This was experienced by most subjects.

The hay fever symptoms were possibly on the basis of circulating antigen also, for the patients had been carefully instructed to avoid inhaling the crude pollen when placing it on their skins. The enhanced sensitization appeared to be lasting, inasmuch as we recently observed the site of an injection test with ragweed pollen and buffered saline solu-

tion to develop a typical eruption which persisted for two weeks. The patient had had a similar rash following her inunction therapy a year before.

Three patients were allowed to go through the season of pollination with no therapy except the course of inunctions. One reported rather good clinical resistance to oak pollen and very good results during the ragweed season. He had taken inunction courses with each of these pollens for many weeks. A second patient experienced a good timothy grass season and a fair amount of improvement in her ragweed hay fever. The third patient likewise reported good improvement in his timothy hay fever. None of these patients showed any significant change in thermostable antibody as the result of their inunction treatments. However, two of the three patients were studied by conjunctival tests of the threshold type and both showed a decided acquisition of immunity following inunction therapy. The remainder of the 10 patients in the group were given regular inunction therapy because serologic studies likewise failed to reveal any acquisition of thermostable antibody for the related allergens following inunctions. The number of patients allowed to go through the pollinating season with no treatment other than inunctions was, of course, too small for us to draw conclusions as to therapeutic effect.

These preliminary experiments bring up the question: What is the immunologic mechanism underlying the untoward reactions in the inunction-treated group? The fact that these responses developed after surface contact puts them into the class of contact allergy; but the nature of the symptoms was such as to suggest atopic vascular allergy related to protein-like allergens. Dr. Sulzberger has referred to his positive inunction tests as resembling "contact urticaria." We may, for the time being at any rate, describe our allergic manifestations as "contact hay fever and contact type of atopic dermatitis." It is to be hoped that Dr. Sulzberger and his collaborators will continue experimenting with this fascinating new tool, the skin-penetrating vehicle, and that out of such work our understanding of the immunologic mechanisms of the various allergies will be expanded.

From a practical point of view, our experiments suggested that the inunction test can serve as a diagnostic aid in pollen allergy, providing the reaction is positive. If it is negative in a patient whose history indicates sensitiveness of a seasonal nature, tests should be performed by the intracutaneous, conjunctival, and/or serologic techniques. Subjects who give definite responses to inunction with these skin-penetrating solutions plus pollen are apt to be highly sensitive in degree and the test can thus warn the physician to administer antigen in a more leisurely manner than he would otherwise employ. There are not infrequent exceptions to this relationship, however, and the test would serve as a crude guide only. As an aid to therapy, it appeared to bring clinical relief to the three patients who took no other treatment. Unfortunately, with the dosage employed by us, the treatment almost invariably provoked untoward allergic reactions. Perhaps smaller doses would obviate this complication of

therapy and still prove effective clinically. The observation that three patients procured a certain amount of clinical relief after inunction therapy but failed to produce circulating thermostable antibody is a challenge which calls for further investigation by those of us who feel that the neutralizing antibody plays some role in the control of hay fever.

It is, of course, possible that tissue immunity was present without detectable humoral immune bodies and that these played a part in the clinical resistance. It is perhaps of real significance that local required immunity was detected in the eye, a shock tissue of hay fever, even when it was absent from the blood. The details of the data referred to in the preceding discussion will be published shortly.

**Dr. Franz Herrmann**—With regard to the desensitization trials, it should be pointed out that Dr. Loveless supplied patients with the plain powdered pollen allergen, which was inuncted with the vehicle at regular intervals, and the patients developed severe, asthmatic or cutaneous reactions. We encountered opposite and very promising results by giving individuals with atopic dermatitis very dilute suspensions of powdered allergen in the vehicle for daily inunctions at home; the initial allergen concentration was 1:10,000, the highest concentration reached gradually was 1:500.

**Comdr. Marion B. Sulzberger**—We are all greatly in debt to Dr. Loveless for her excellent work and fine report, and I want to thank her personally for her discussion. There is no great discrepancy between Dr. Loveless' findings and ours. When we tested a few patients who were negative to scratch tests but positive to intracutaneous tests we found that the correspondence between our inunction tests and the intracutaneous tests was only about 50 per cent; i.e., we had approximately 50 per cent false negatives in the few cases in which we used the reactions to intracutaneous test as a base line, in contrast to the 100 per cent correspondence between the scratch test reactions and the inunction tests with the latest and best D-type vehicles.

We hope that Dr. Loveless and others will continue with this work and see whether, when they use the latest D-type vehicles they find that there is such close correspondence between scratch test and inunction test reactions also in their hay fever, asthma, and other patients. Unfortunately, our own clinical material consists almost exclusively of atopic dermatitis patients; and, as I have tried to emphasize, their skins may well be generally below normal in their resistance to penetration.

Only time and study will tell what the practical value of our vehicles may be, either in skin tests or desensitization therapy, for vaccination or immunization with toxins or toxoids, for accelerating patch test reactions, for venereal disease prophylaxis, for treating fungous and other affections of hair or nails, or for any other medical or other purposes. We make no assertions or claims as to their practical value today. But we do know that these vehicles carry many substances, including the so-called protein allergens, into and through the skin at a much greater rate than has been possible with other vehicles. Based on this established fact, we recom-

mend these vehicles for study and possible application to any situation in which accelerated and inten-

sified percutaneous penetration may be expected to prove interesting or valuable.

## ANESTHESIA FROM BRITAIN

We are prone to consider anesthesia and all its works as American products. As a consequence we sometimes forget the part played by a kindly but dogged Scotch physician Dr James Y Simpson

ago, on January 19, covered ether in the ber 15, 1847, having like a good anesthe-

but not thus in-rities who quoted

he retorted "To him that knoweth to do good, and doeth it not, to him it is sin." He prevailed, and subsequent to his delivery of Queen Victoria under chloroform he was knighted.

Sir James approached his problem scientifically. He recognized the objections to ether, but before introducing a new agent, he first tried this out on himself and his friends. The dangers of chloroform were not unknown to him, and therefore in spite of the good results, he continued his search for a still better agent.

Seven advantages over ether were claimed for chloroform: (1) smaller dosage, (2) quicker action, (3) more agreeable sensation, (4) decreased cost, (5) evanescent odor, (6) ease of transportation, and (7) simplicity of administration. He states in *Anaesthesia and Hospitalism*, "I have found, however, one infinitely more efficacious than any of the others—viz., chloroform or perchloride of formyle—and I am enabled to speak most confidently of its superior anæsthetic properties, having now tried it upon upwards of thirty individuals."

ple results, since it well as good," and i, and the counter-

Sir James investigated at least five other chemical agents. In their anæsthetic properties he concluded "They are more interesting physiologically than therapeutically."

We would remind British contributors to this issue that we acknowledge a great debt to Simpson and chloroform. If Simpson had "exhibited it or been present when it was exhibited, in several thousands of instances" before he met with a fatality, with our increased knowledge of physiology and

a

sh

ed list of anæsthetic agents. The discriminating anæsthetist recognizes that both agents have disadvantages, but one hundred years have not diminished their advantages.

And so we remain grateful for the contribution of chloroform from over the sea—*Editorial by Howard Dillrick, M D, in Anesthesia & Analgesia, July-Aug, 1944*

## ILLS OF AIRMEN AT HIGH ALTITUDES

The Aero Medical Association met in St. Louis recently and discussed some of the new and difficult medical problems that must be faced when fliers ascend to heights of 35,000 and 40,000 feet. Among the more serious problems are those presented by

by the

ade by

Colter

and Sur-

geons).

Two of the physicians sat in a tank from which the air had been partially exhausted so that the pressure was no more than that which prevails at 42,000 feet. One physician thus subjected himself periodically to test for seventeen months, the other for three. Both contracted tuberculosis.

The scars of healed lesions, often present in normal persons, burst open, for reasons not clear. Possibly the pressure of gases within the scars is the explanation, possibly nitrogen in the blood stream.

The "chokes" are accompanied by coughing and difficulty in breathing. Without an oxygen mask an afflicted man would die. But since he cannot keep the mask on he drops to a lower altitude, where he may be blown to bits by an anti-aircraft shell.

Lt. Col. A. P. Gage of the aero-medical laboratory at Wright Field, Dayton, Ohio, described the Army's new pressure mask, which has hitherto been shrouded in dense military secrecy. Probably the Germans have captured men who wore the masks, so it was safe to give the association the details of their construction.

This new mask does half a man's breathing for him. That is, his lungs are blown up like balloons so that he does not have to inspire. When he exhales he uses his breathing muscles in the normal way.

1

2

At 50,000 feet consciousness was usually lost. Even with the new mask, air crews are good for not much more than half an hour at 45,000 feet. Ex-

small amounts of carbon monoxide are harmful to

oxide may come from engine exhaust gas, tobacco

smoke, or gunfire. It is harmful because it reduces the oxygen-carrying ability of the blood and so in-

creases the ever-present danger at high altitudes that the brain may not get enough oxygen for proper functioning—W. K., in the New York Times,

# FRACTURE OF THE NECK OF THE FEMUR

## A Surgical Technic for Reduction and Internal Splinting by Direct Visualization

SAMUEL KLEINBERG, M.D., F.A.C.S., New York City

THE management of a recent fracture at the hip is still an incompletely solved problem, although splendid progress has been made in recent years. Prior to the advent of the abduction method there had been an attitude of indifference and a feeling of defeatism. Consequently, the treatment of a fracture at the hip was characterized chiefly by a lack of treatment. Many of the patients disabled by this fracture remained confined to bed, and sooner or later developed hypostatic pneumonia or pressure sores and infections to which they succumbed. Others, because of or in spite of the poor treatment, managed to get about but remained crippled for life. A few only, presumably patients with fractures in which there was little or no displacement, obtained reasonably good function. When Royal Whitman devised and advocated the abduction method, he initiated an interest in the treatment of this fracture which has persisted and has stimulated many surgeons to devote themselves to the therapeutics of this injury.

To Royal Whitman belongs the credit for insisting on an active program of treatment to be instituted as soon as the patient has recovered from the shock of the injury. He believed that a fracture of the neck of the femur should be treated like any other fracture. The fragments should be brought into good alignment and the limb immobilized in a reliable apparatus. In this way the surgeon can provide the opportunity for repair and healing of the fracture.

The abduction method depended on this principle of immediate reduction and immobilization. It consisted of manipulation of the limb by traction, internal rotation, and abduction. The fragments were realigned by traction and internal rotation. Abduction tensed the capsule, which helped to maintain intimate contact of the fragments. A long plaster-of-paris spica bandage was then applied to immobilize the hip and maintain the reduction until the fracture healed or there was evidence of absorption of the neck and inevitable nonunion. The plaster spica also served to keep the patient free from pain and to permit change of position to avoid hypostatic pneumonia. With this method many fractures healed.

The abduction method, however, had several manifest drawbacks. The incidence of union was unpredictable. The plaster dressing had so

much padding for the protection of the patient's skin that it often became loose, and allowed undesirable motion of the fragments so that slipping of the fragments could and at times did take place within the plaster. The patient was compelled to remain continuously in the recumbent position. Therefore, modification of the abduction method and new procedures were sought.

A very distinct advance was introduced by Leadbetter, who employed a more accurate method of reduction, less abduction, and a skin-fitting plaster spica. I added early weight-bearing to the Leadbetter method. This enabled me to take the patient out of bed a day or two after the reduction. The patients were much happier because of the change of the position, and many rapidly learned to walk well, and enjoyed a measure of independence. The most important effect of the improvement on the original abduction method was the increased contact of the fragments, which favored more rapid vascularization and union.

The utilization of metal plates for the immobilization of fractures in various parts of the skeleton stimulated the attempt to provide an internal splint for fractures at the hip. Hence there came into use the Smith-Peterson and other types of nails as well as wires and screws. My interest in the use of a nail to immobilize the fragments was aroused several years ago when on a visit to Los Angeles, Dr. Vernon P. Thompson exhibited to me a Z-nail which he had devised, and a simple and relatively easy operative method of reduction and fixation of the fragments by his nail through direct visualization of the fracture. My associate, Dr. Joseph Buchman, and I have applied this method rather frequently in the last two years, and I wish to describe it here in detail, because, of all the methods of nailing a fractured hip, this one appeals to me as the simplest. It does not involve the use of accurate measuring apparatus and, even though it is advisable to have checkup films made at the time of the operation, one can, if necessary, reduce the fracture and insert the nail with reasonable and adequate accuracy without the aid of roentgenograms.

The operation can be performed under general, spinal, or intravenous anesthesia. The nail (Fig. 1) is 10 inches long, and  $\frac{3}{4}$  inch wide, and its cross section is Z-shaped, as a result of which the nail gets a grip on the bone in several

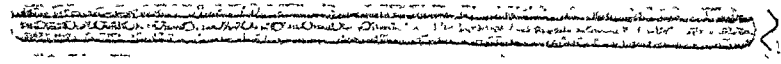

FIG. 1. Z-nail devised by Dr. Vernon P. Thompson. The nail is 10 inches long. One half of it is perforated by holes spaced 1 cm. apart. The cross section is the shape of a Z. The metal is stainless steel.

planes, and tends to remain in the position in which it is placed, fixing and holding together the fragments. The nail, being much larger than the segment required for the fracture, is rather easily inserted. The excess is cut off with special shears about  $\frac{1}{2}$  inch beyond the cortex of the femur. This exposed section is cut vertically and bent over the femur in opposite directions by pliers. The distal half of the nail, that is, the part inserted into the bone, is perforated every centimeter for five inches to facilitate easy calculation of how far the nail must be driven in. Moreover, if the nail has been inserted incorrectly it can be withdrawn by the use of a nail extractor which fits into the perforations in the nail, and reinserted in a more favorable direction. The nail is made of stainless steel and is nonirritating. In none of my cases has there been any evidence of bone absorption through electrolytic reaction.

### Technic of Reduction of the Fracture and Insertion of the Thompson Z-Nail

The patient lies on his back with sandbags under the hip and chest on the side to be operated upon. An oblique incision is made over the anterolateral aspect of the hip (Fig. 2). The incision is about 7 inches long. It begins just below and behind the anterior superior iliac spine and extends somewhat obliquely downward and backward over the anterior border of the greater trochanter and on down the thigh to about 2 inches below the base of the greater trochanter. The incision is extended through the fascia, exposing the interval between the tensor fascia femoris and the gluteus medius, the former of which is retracted forward and the latter backward, exposing the front of the hip joint. The vastus lateralis, which comes into view at the base of the greater trochanter, is either cut transversely and stripped downward for about  $1\frac{1}{2}$  inches, or vertically and the upper part of the femoral shaft is exposed by subperiosteal retraction of the split muscle. In the interval between the tensor fascia femoris and the gluteus medius there comes into view some areolar tissue and directly beneath it the capsule of the hip joint. The capsule is incised and retracted, giving a full view of the fracture and the

relationship of the capital and cervical-fragments (Fig. 3). By gentle traction and internal rotation of the limb the fragments are readily brought into accurate apposition and intimate contact (Fig. 4). Parenthetically it may be stated that it is remarkable how little force is necessary to reduce the fracture, and how little abduction, rarely more than 20 degrees, is required to maintain good apposition of the fragments. Twenty-five years ago we used to be under the impression that an extreme degree of abduction, 60 to 70 degrees or even more, was indispensable to assure the reduction. Later Leadbetter showed that the reduction, once accomplished, could be retained by moderate abduction. Now we know that if the reduction is satisfactory and is assured through an internal splint, as a Thompson nail, one need not be concerned about any large degree of abduction of the limb.

One now proceeds with the insertion of the nail. It is inserted on the middle of the outer surface of the femur at the base of the greater trochanter and is directed toward the middle of the head (Fig. 4). Since the hip joint is exposed and one can see the head and neck, it is relatively simple to point the nail so that as it enters the neck and head it will be well within the substance of these fragments. Before driving the nail into the fragments one lays it on them and decides how far the nail must go to reach the subchondral part of the head and makes a mental note of the distance by seeing which of the perforations is opposite the outer surface of the femur. After the nail has entered the head one can test the security of the fixation by rotating and flexing the limb and actually seeing the head move with the neck, and assuring oneself of the security of the reduction and contact of the fragments. One cannot be absolutely positive that the nail has been driven in far enough; that is, into the subchondral region of the head. Therefore, it is well to have checkup x-ray films of the hip made in the anteroposterior and lateral planes. In a well-equipped service this takes only a very few minutes, perhaps five. If one finds that the nail is not in quite far enough, it is a simple matter to drive it in the additional required distance. The nail is then cut off about  $\frac{1}{2}$  inch from the outer surface of the femur. The projecting portion of the nail is then bent down over the

FIG. 2. Note the scar on the lateral aspect of the hip which indicates the line of the incision. It begins behind and below the anterior superior iliac spine and extends down over and below the greater trochanter.

femur. Thus is created a broad head to the nail. In fact, the ends can be driven into the cortex of the femoral shaft and thus motion of the nail can be permanently prevented.

In the above procedure there is very little bleeding, because the approach to the hip has been through an intermuscular plane. The wound is now rapidly closed in layers. The entire procedure takes about twenty to twenty-five minutes, including the roentgenography. There is little shock and even debilitated, elderly people tolerate the operation very well. I consider this operation certainly no more and probably much less shocking than the closed manipulative reduction. Nailing takes no longer than the closed reduction and plaster immobilization in the hands of an experienced surgeon.

In most instances no additional support is required. If, however, one has encountered much comminution, it is advisable to apply a short plaster-of-Paris spica for a few weeks.

FIG. 3. Exposure of the fracture in the interval between the tensor fascia femoris anteriorly and the gluteus medius posteriorly. The capsule is cut and retracted. The fracture and the displacement of the fragments are outlined.

The postoperative care is exceedingly simple, because the patient has lost all pain and the limb may be moved reasonably freely, both actively and passively. On the first postoperative day the patient is allowed to sit up in bed. On the second or at most the third postoperative day the patient may be taken out of bed and placed in a wheel chair for an hour or more. Thereafter the patient sits up in bed for every meal and is taken out of bed once or twice a day.

About two weeks after the nailing the patient is allowed to stand up either in a "walker" or with crutches. Standing becomes a daily practice, and after one week of standing the patient begins to walk bearing weight on the injured limb. It is surprising to see how rapidly and how well the patients learn to stand and walk. There may be an occasional twinge of pain in the thigh or knee, but most of the time the patient is free from pain and is willing and anxious to walk. Several of my patients have been able to walk without any crutches or even a cane within three to four weeks.

The element of weight-bearing is, in my judgment, an important feature of the treatment because, through this medium, the closeness of the contact of the fragments is increased and thereby assured. Moreover, the closeness of the fragments facilitates the vascularization of the area of the fracture and the capital fragment, and hastens the healing. Prior to my use of the Thompson nail I combined early weight-bearing

FIG. 4. Visualization of reduced fracture and insertion of the Thompson nail. The nail should extend to the subchondral area in the femoral head.

FIG. 5. Case 1. M. S. Typical transcervical fracture with upward displacement and outward rotation of the shaft.

with the Leadbetter reduction and skin-fitting plaster spicas. I found that healing took place remarkably rapidly and recall only one case in which union did not occur. The weight-bearing serves to impact the fragments. The only potentially poor result is that there may be some shortening of the neck, presumably from the impaction. But by the same token the impaction favors early union. The objection to weight-bearing that has been raised in some clinics is, I think, entirely theoretic. It has been assumed that the capital fragment, deprived of a normal blood supply, undergoes aseptic necrosis. In this weakened state weight-bearing would cause compression and deformity of the head. My experience, however, teaches me that under the circumstances I have described the head does not undergo aseptic necrosis, does not become deformed, and does unite with the neck. Hence I favor early weight-bearing in a fractured hip when the fracture has been properly reduced and the fragments thoroughly immobilized.

The advantages of the Thompson method of open reduction of a fracture of the neck of the femur and the insertion of a Z-nail combined with early weight-bearing appear to me to be the following:

1. It is simple, because the operative approach is through an intermuscular plane.
2. The alignment of the fragments is accomplished through gentle manipulation.

3. The reduction is performed under direct view of the fragments.

4. The insertion of the nail is facilitated by the fact that the surgeon can, during this process, continuously see the fragments and know when the nail has engaged the femoral head.

5. Adequate fixation of the fragments can be confirmed clinically by seeing the head and neck of the femur move simultaneously when the limb is rotated, flexed, and abducted, and roentgenographically by immediate checkup x-ray films.

6. The opportunity for gentle manipulation of the limb and the tissues made possible by a free exposure of the fracture results in minimal operative trauma and postoperative disturbance.

### Case Reports

*Case 1.*—Mrs. Marie S., 76 years old, fell and fractured her right hip on January 10, 1941. I saw her a few hours after the injury and found all of the classic clinical evidences of a fracture at the hip with one inch of shortening of the limb. An x-ray film (Fig. 5) showed a transcervical fracture. She was promptly admitted to the Hospital for Joint

FIG. 6. Case 1. X-ray film made during the operation. It shows the nail driven through the femoral neck in the direction of the head. At this stage it is easy to calculate how much farther the nail must be inserted to reach the subchondral area in the femoral head.

FIG. 7. Case 1. X-ray film three months after the operation. It shows the reduction of the fracture being maintained. The rough outer extremity of the nail is the level at which it was cut off and bent over the cortex of the femur.

FIG. 8. Case 2. Severe comminuted trans-cervical fracture with marked outward rotation and upward displacement of the femoral shaft.

FIG. 9. Case 2. Fracture well reduced. Nail not inserted far enough. It should have been driven in at least another  $\frac{3}{4}$  inch.

FIG. 10. Case 2. Nail maneuvered well into the capital fragment by traction and abduction

FIG. 11. Case 2. Shows patient able to sit comfortably less than three months after the operation.

Diseases and operated upon the following day. Fig. 6 is a copy of a checkup x-ray film made during the operation. It shows a complete reduction of the fracture and the nail driven in the right direction but not having engaged the head sufficiently. The perforations in the nail aided in rapidly determining how much further the nail had to be inserted. The operation was performed under general anesthesia.

The patient reacted well after the nailing but several days later exhibited signs of a pneumonic process in the right lung. This disturbed her physicians much more than it did her, for she had no complaints and was apparently not very uncomfortable. She responded well to the administration of the sulfa drugs, and at the end of two weeks was well enough to be taken out of bed and placed in a wheel chair. Thereafter she was out of bed every day and in less than a week she was taken home. She rapidly learned the use of crutches and was allowed to walk a few minutes several times a day. The extent of the walking was increased daily. In less than a month after she came home she could and did walk across her room rapidly and without any discomfort. At present, less than three months after the accident, she has a full range of motion in the hip, no shortening of the limb, walks liberally during the day, and gets into and out of an ordinary chair without assistance. She has even walked up and down a whole flight of steps. The roentgenogram (Fig. 7) shows good alignment of the fragments.

Case 2.—Sam G., 61 years old, was admitted to

the Hospital for Joint Diseases on January 15, 1944. Several days previously he had fractured his left hip (Fig. 8) and three ribs. On admission he had a temperature of 101.4 F., apparently caused by an upper respiratory infection. Because of the elevated temperature the operation was postponed until January 18, when it was performed under spinal anesthesia. The clinical manifestations of the hip fracture were classic, including shortening of the limb of 1 inch.

At operation the fracture was found to be of the comminuted variety. However, the fragments were easily aligned and a Thompson nail was inserted (Fig. 9).

The patient was taken out of bed on the third postoperative day, and daily thereafter. He developed the habit of holding the injured limb continuously in adduction. Not enough attention was paid to this fact until the eighteenth postoperative day when a checkup x-ray film showed what appeared to be a slightly lateral displacement of the nail in the capital fragment. In retrospect the nail was not driven into the head sufficiently far (Fig. 9), so that its hold on the head was not secure. Traction in abduction was promptly instituted and several days later a supporting plaster-of-Paris spica bandage was applied. At this time the nail was well within the head (Fig. 10). He rapidly learned to stand and walk.

FIG. 12. Case 3. Severe transcervical fracture.

FIG. 13. Case 3. Reduction of fracture and insertion of the Thompson nail.

FIG. 14. Case 3. This film was made six weeks after the operation. Compare with Fig. 13. The neck has been shortened by the impaction of the fragments through walking and weight-bearing.

FIG. 15. Case 3. Shows patient able to sit normally in a straight-backed chair.

The plaster spica was left on until April 7, 1944, when a roentgenogram showed satisfactory alignment of the fragments and the fracture healing. There was no shortening of the limb and the range of motion in the hip was about half of the normal. The patient was able to sit reasonably well (Fig 11) and enjoyed walking, which he did for several hours a day without discomfort or undue fatigue.

**Case 3**—Mrs B H, 60 years old fractured her left hip on February 13, 1944, and was operated upon several days later. She had sustained a severe, comminuted fracture (Fig 12). The fragments were brought into close contact and a nail was inserted (Fig 13). Because of the comminution a short plaster spica was applied and left on for several weeks. A checkup x ray film made on March 27, 1944 (Fig 14), about six weeks after the operation, showed the fragments to be in good contact and uniting. The fragments have been impacted by the walking and weight-bearing, as is shown by the fact that the neck is somewhat shorter than it was in the film made six weeks previously (Fig 13).

The patient began walking with crutches two weeks after the operation and continued daily. At present, a little over two months after the operation, the patient is home, walking about freely and without any discomfort. There is no shortening of the limb. She is able to sit in a straight-backed

chair (Fig 15) and has an extensive, although not quite normal, range of motion in the hip.

### Summary

My chief interest in this presentation is again to direct attention to the treatment of fracture of the neck of the femur. My main concern is with the philosophy of the treatment and more particularly with the change in the general attitude of therapy from the conservative to the operative management, which marks a distinct advance in the solution of a difficult problem. It is my belief that in all but the exceptional cases the open reduction of the fracture and the internal splinting of the fragments constitute a procedure which now supersedes all previous conservative measures. I desire especially to emphasize the simplicity and effectiveness of the surgical technique and the Z-nail devised by Dr. Vernon P. Thompson. Last, I wish again to recommend the institution of early weight-bearing in the management of a cervical fracture at the hip because, when the fragments have been properly aligned, intimately contacted, and adequately immobilized, early weight-bearing serves to further impact the fragments and hasten healing.

### THE PREVENTION OF CANCER

In a recent and interesting discussion<sup>1</sup> of preventive medicine occurs the statement:

"Prompt and aggressive treatment—a purely curative process—takes on a strongly preventive coloring because it may forestall serious deterioration or death. This is true also of cancer, a non-preventable disease of unknown cause which can

intervene at a profitable stage in many cases of cancer which would otherwise go unrecognized until they were incurable. The gastrointestinal x ray study which a careful diagnostician orders when confronted with certain abdominal symptoms is thus an important tool of preventive medicine."

Suffering and death from cancer are prevented by its cure and in that respect cancer is preventable. But the remark that cancer is a nonpreventable disease, presumably in the sense that its onset cannot be prevented, and of unknown cause is open to question.

The causes of cancer are by no means unknown. Experiments have demonstrated that a large number of substances can cause cancer. True, the exact mechanism of cancer causation is not understood. Neither do we understand just how the tubercle bacillus causes tuberculosis. Our knowledge of these and other more or less similar mechanisms is as yet mainly in the observational and descriptive stage.

There are many examples of cancer in man that

arise under the influence of particular agents under such circumstances that there can be no doubt as to cause and effect. One of these is chimney sweeps' cancer of the skin, recognized by Percival Pott in 1775 as due to the action of soot, from which carcinogenic chemicals have been isolated in recent times. Other examples are mule spinners' cancer, due to mineral oil, cancer of the skin in tar workers, cancer of the lip in fishermen repairing tarred nets, cancer in workers with aniline dyes, and cancer in x ray and in radium workers. In other cancers the causative condition is obvious but the precise agent is not known. This is the case of cancer at a spot where the mucous membrane of the mouth has been rubbed by a ragged tooth or an ill fitting denture or at the spot on the cheek against which the quid of chewing tobacco has been held perhaps for years. In cattle cancer may arise at the root of the horns where the traction rope runs back and forth. In industries carcinogenic chemicals are used which on entrance into the bodies of workers may cause preventable cancer. The successful results of planned experiments could not be more convincing of the preventability of human cancer than these and other clinical examples. Generally speaking, the association of cancer with chronic inflammatory and irritation lesions—"precancerous conditions"—is so close that their prevention and

clinics for cancer prevention. All the efforts to control cancer are based on the possibility of preventing its start as well as its advance.—*Editorial, J.A.M.A., Aug 28, 1944.*

# AN EVALUATION OF THE USE OF CURARE IN ENDOSCOPY

JOSEPH S. SILVERBERG, M.D., and F. PAUL ANSBRO, M.D., Brooklyn

CURARE has been utilized in the practice of anesthesiology because of its relaxing effect on the striated musculature. Cullen<sup>1</sup> stimulated our interest in the subject when he reported some cases in which he successfully used this preparation for this effect in endoscopic procedures. This presentation concerns itself with the use of curare in endoscopy.

Curare is a drug used by the South American Indians as an arrow poison. It is extracted from the bark of certain plants. The active principle, isolated by King, is described as a crystalline quaternary base chloride designated by him as d-tubocurarine chloride.<sup>2</sup> It acts physiologically by interrupting the nervous impulses at the neuromuscular junction. It is believed that this is brought about by a neutralization of the acetylcholine reaction. This, in turn, constitutes the fundamental neuromuscular stimulation mechanism.

It is claimed that curare is of value in endoscopy because of its progressive action. After administration, it is noted that certain muscles of the head and neck relax before paralysis of the respiratory muscles and the muscles of the extremities develops. In man,<sup>3</sup> shortly after administration, a weakness of the extraocular muscles and lids is noted, speech becomes thick and nasal, and swallowing is impaired. Soon it is difficult and then impossible for the patient to raise his head from the table; muscle strength is now found to be markedly impaired. This sequence usually follows in approximately two minutes after intravenous injection.

There is apparently no direct effect on the cerebrum, while a moderate fall in blood pressure of 5-10 mm. of mercury and a 5 per cent increase in the pulse rate is noted. These return to the normal level on discontinuing the drug.

West<sup>4</sup> has reported bronchial spasm when curare is used. Previously, Trendelenburg had stated that bronchial muscle was not affected by curare.<sup>5</sup> We have encountered one patient who had bronchial muscle reaction with the preparation we have been using. It is said to be free from elements that cause significant cardiac depression.

In the application of the drug, it was considered advisable to choose the intravenous route in order to obtain the maximum effect quickly

and to aid in determining the proper dosage. In our first series, we began with 10 to 20 mg. and increased the dosage gradually. With this conservative technic we found that we could not obtain sufficient concentration of the drug in the blood-stream to paralyze the neck muscles so that the patient was unable to raise his head from the table. When injected so slowly, the drug appeared to be detoxicated and eliminated as it was given. Therefore, in our second series we administered the minimum dose of curare as it is used in psychiatry to soften convulsions in metrazol shock therapy. Curare was injected intravenously, in a dosage of 0.5 mg. per pound of body weight less 20 mg. for the initial injection. The dosage was then increased until the full physiologic effect was obtained. The upper limit was 0.75 mg. per pound of body weight. In only one case was this limit exceeded slightly. The injection was performed slowly over a period of one to one and one half minutes. Each additional injection was given after waiting a full two minutes. Some means of applying artificial respiration with oxygen and carbon dioxide was kept close at hand. Patency of the airway was also constantly maintained. No patient was left alone until consciousness was fully regained.

In the event of respiratory failure, we were always prepared to administer artificial respiration immediately, with the addition of prostigmine in a 1:2,000 dose. The prostigmine is employed to counteract the effect of an overdose of curare.

Atropine was given prior to the injection to block the muscarinic action of the drug. The usual preoperative sedation, such as the barbitals, was also administered. It is not advisable to combine morphine with the barbitals lest the combination with curare produce an overdepression of the respiration.

Patients who have myasthenia gravis are said to be extremely sensitive to the drug. One fifteenth to one fifth of the average adult dose may produce a profound exaggeration of symptoms.

Although Cullen applied the drug in children, we excluded children from this series. More than half of our patients were past sixty. We note the fact that many of our patients were not as good surgical risks as those from other hospitals. In the past, however, we have not had much difficulty in performing bronchoscopy or esophagoscopy on this type of patient.

## Case Reports

Cases 1-4.—The first 4 cases in our series (Table 1) included 2 men, 53 and 65 years of age respec-

\*\* Complete inability to lift the head.

† Ability to lift the head three fourths of way.

tively, and 2 women, 46 and 21 years of age respectively. In this group,  $1\frac{1}{2}$  grains of nembutal and  $\frac{1}{4}$  grain of morphine sulfate with  $\frac{1}{150}$  grain of atropine were given prior to bronchoscopy. The larynx and trachea were anesthetized with 10 per cent cocaine solution. We began with a small dose of 10-20 mg. and increased it to 50 or 60 mg. of the drug.

Because we were unable to obtain the complete physiologic effect, which is evidenced by the inability of the patient to lift his head, we changed our routine in the next series to that suggested for metrazol therapy.<sup>6</sup>

*Case 5.*—Applying this changed technic in a patient who weighed 111 pounds, to whom we administered 45 mg., we were successful not only in producing the full physiologic effect on the muscles which lift the head, but there occurred a complete paralysis of the respiration with cyanosis, thready pulse, and a period of apnea for one and one-half minutes. Artificial respiration was carried out and prostigmine was administered. The patient regained full consciousness in thirty minutes. We concluded that the combined effect of the morphine, nembutal, and curare resulted in an overdepression of the respiratory mechanism. The following week we repeated the procedure on the same patient without morphine. Thirty milligrams produced a full physiologic effect with good relaxation for the bronchoscopy. Therefore we discontinued the use of morphine in the remainder of our series.

Out of the remaining cases the following experiences are of interest.

*Case 9.*—A woman, aged 52, and weighing 187 pounds, was subjected to esophagoscopy for a retroesophageal abscess. She was given 104 mg. of curare before complete relaxation of the head was produced. Shortly after insertion of the esophagoscope, she developed cyanosis, generalized convulsions, and a thready pulse. This was relieved after several minutes of artificial respiration followed by oxygen therapy. Esophagoscopy, without curare, was repeated several days later. No difficulty was encountered.

*Case 10.*—This is the only case in the series in which the dose of 0.75 mg. per pound of body weight was exceeded slightly. In spite of this dosage, the stage of complete relaxation of the head could not be reached. We experienced considerable difficulty in performing the bronchoscopy. This could be attributed to the fact that the cocaineization was inadequate. This experience confirms the observation made in previous studies that satisfactory anesthesia must be obtained prior to the use of curare. The drug has no analgesic effect.

*Case 11.*—This case demonstrates that in some patients the complete physiologic effect may require more than two minutes to manifest itself. Although there was incomplete effect prior to bronchoscopy, full relaxation was present on completion of the procedure.

*Case 15.*—This history is of interest. A total dose of 100 mg. was injected. As in Case 9, the patient developed cyanosis and then progressed to the stage

of convulsions, which began about the face and then became generalized; the chest was fixed and there was no respiratory exchange; coma ensued rapidly. The pulse became rapid and then very weak and thready. The suck-and-blow resuscitator, using carbon dioxide, was applied for about twenty minutes. Coramine, caffeine, glucose and saline, and prostigmine were administered intravenously. There was no satisfactory response and the patient continued in apnea. A flexible tube was inserted into the trachea and artificial respiration was continued, using 10 per cent carbon dioxide and oxygen. After an interval of one-half hour during which there was no improvement, the patient was transferred to a Drinker respirator where he at first received 7 per cent carbon dioxide and oxygen, and then 100 per cent oxygen. The artificial respiration in the Drinker respirator was discontinued after two hours, at which time he began to breathe unaided. Oxygen therapy, by mask, was maintained for three hours more when the laryngeal reflexes returned and the intratracheal tube was not tolerated. The patient's mind was confused for twelve hours, after which full mental and physical recovery followed.

The following paragraph from Cushny's *Pharmacology*<sup>7</sup> is of interest. "In the mammal, eventually the respiration ceases and asphyxia follows but is not betrayed by the usual convulsions owing to the motor impulses being unable to reach the muscles. The heart soon fails from the asphyxia and not from the direct action of the poison."

This seems to suggest that the convulsions noted in our cases may be the result of partial asphyxia rather than direct curare poisoning. However, Goodman and Gelman<sup>8</sup> state: "Curare stimulates the central nervous system. Strychnine-like convulsions are seen after the use of some samples of curare, and picrotoxin-like spasms after others. Ordinarily, however, convulsions are masked by the peripheral muscular depression." In our cases, the convulsions were very pronounced and were generalized. Sollman<sup>9</sup> has stated that "curare may produce a number of side effects resembling nicotine in depressing autonomic ganglia (vagus), and strychnine in stimulating the spinal cord."

*Case 17.*—This is the only example of the development of spasm of the larynx after the administration of the drug and prior to bronchoscopy. Because of massive atelectasis of one lung, considerable breathing difficulty was noted from a dose of 35 mg. Therefore, no additional drug was given.

*Case 18.*—This is a case of atelectasis of the right lower lobe with an emphysematous type of chest. After a dose of 80 mg., the patient developed paralysis of the intercostal muscles with cyanosis and slight generalized convulsive twitchings. The resuscitator was applied with an intratracheal tube in place. Prostigmine was administered. The patient was out of danger in twenty minutes.

*Cases 19 and 20.*—Finally, in the last 2 cases, after injecting 0.5 mg. per pound of body weight, minus 20 mg., we increased each additional application by 10 mg. instead of 20.

This appeared to be a less hazardous method of administration.

## Summary

Twenty cases are presented, in which twenty-one administrations of curare were given. The following points are noteworthy:

1. A satisfactory local anesthesia for endoscopy must be obtained prior to the use of curare.

2. Morphine should not be used prior to endoscopy when this drug is employed.

3. The dosage varies considerably with each patient. We therefore recommend a first injection of 0.5 mg. per pound of body weight, less 20 mg., increasing each injection by 10 mg. Each injection should be prolonged for a period of one to one and one-half minutes. It is advisable that the full two minute period elapse between additional injections.

4. Finally, curare is to be used with caution prior to endoscopy in patients with a marked diminution in tidal exchange. Cyanosis with convulsions occurred in 3 cases of this type, while difficulty in breathing manifested itself in 2 such additional cases.

## Conclusion

Curare relaxes the striated musculature and may be useful in troublesome endoscopies. On the other hand, since it is difficult to determine the exact dosage for each patient and since the effects of the drug are so unpredictable, we do not feel that curare may be used for endoscopy with safety. To obtain relaxation for endoscopic procedures we prefer other measures, such as adequate preoperative medication with barbiturates by mouth and morphine and atropine by subcutaneous or intravenous injection, or by the use of intravenous barbiturates.\*

\* The curare preparation used in this report is marketed under the name Intocostat.

## Discussion

Dr. M. C. Myerson, New York City.—Whenever a new procedure or a modification is contemplated several things must be considered: first, whether or not it is really necessary; second, whether it is safe; third, whether it is practical; and last, whether it is really of value. When performed by the properly trained man, bronchoscopy is usually done so smoothly that special medication to relax the patient, other than use of one of the barbiturates, should not be necessary. We give our patients 3 grains of nembutal one-half hour before bronchoscopy, as a result of which we rarely encounter any difficulty.

Dr. Silverberg's presentation has impressed you better than I can with the tremendous danger involved in the use of curare for bronchoscopic cases. Whether it is because so many of the patients referred for bronchoscopy have a lowered vital capacity, or whether curare acts differently when the patient is awake, I do not know. I have asked a number of practitioners for the explanation of the comparative safety in the use of curare as an adjunct to general anesthesia. They could not explain why it is so safe in this group as compared to the bronchoscopic cases. I had the privilege of performing bronchoscopy on some of Dr. Silverberg's patients. I was strongly impressed by the suddenness of the paralysis of the intercostal muscles and of the very few seconds which elapsed between the patient's inability to lift his head and the appearance of this paralysis. If it had not been for the presence of an expert such as Dr. Ansbro, we would have been in a serious dilemma. If, after this report, anyone will permit the use of curare for bronchoscopy, I would urge him to be sure to have an anesthetist and his resuscitating apparatus present.

The use of curare for bronchoscopy is not practical because it takes at least twenty minutes for the proper administration of the drug, a great majority of bronchoscopies can be performed in much less time than twenty minutes.

Furthermore, I was impressed, during bronchoscopy, with the fact that whereas the bronchoscope readily passed through the larynx before curare was administered, difficulty was encountered because of spasm of the vocal cords which had not existed before. Even if the use of curare was completely free of danger, the number of bronchoscopic cases in which difficulty is encountered because of lack of relaxation is so small as to nullify the value of such an adjunct. I would summarize my remarks by saying that if bronchoscopy had to be done with curare, I would prefer not to perform bronchoscopy.

# FUNDAMENTAL CHARACTERISTICS OF THE DIFFERENT MEDICOLEGAL SYSTEMS IN THE UNITED STATES

B. M. VANCE, M.D., New York City

THE subject which I discuss in this paper is of considerable importance to the medical profession and to the community at large, because it is a brief appraisal of the different medicolegal systems under which suspicious and violent deaths are investigated by the county governments in the United States. In most counties these investigations are under the supervision of an elected official known as the coroner, who has a minor judicial status. In a few communities such duties are assumed by physicians known as medical examiners, who are appointed officers of the county government, and who conduct their investigations on a totally different basis from those of the coroners. In recent years there has been a tendency for an increasing number of communities to look with dissatisfaction on the coroner system in their midst and to consider a change to some form of the medical-examiner system.

A consideration of these different systems is, therefore, a matter of something more than academic interest, because with the growing complexity of civilization an efficient method of investigating violent and suspicious deaths becomes highly desirable. Accordingly, it is my purpose to review briefly the history and present status of these different systems in an endeavor to discover which one is best adapted for its purpose.

## Coroner System

The coroner was originally an official with magisterial powers appointed by the king to represent the English Crown in a certain district. The office dated from about the period of the Norman conquest, and its incumbents were men of high station and enjoyed great prestige. Their duties were to see that the Crown obtained due recognition in cases where money was involved, as in the discovery of treasure or in the investigation of crimes punishable by fines. If any violent or suspicious deaths occurred in his jurisdiction, the coroner was informed, and a jury was summoned from the neighborhood; the coroner and jury then viewed the remains, and the coroner made an investigation into the circumstances of death. If the evidence was sufficient to charge a person with the crime of homicide, the duty of the coroner was to confiscate the chattels of the accused

for the Crown. In like manner, if a person suspected of a crime became a fugitive, whether guilty or not, the coroner was empowered to declare him an outlaw and seize his goods and chattels. Even in cases of misadventure, if a domestic animal or a movable object was instrumental in causing the death of a person, it was forfeited to the Crown under the name of a deodand; similarly, all the property of a suicide was seized as a deodand. Incidentally, deodands were only abolished in the nineteenth century under the impact of the rising industrial age, when it was found inconvenient to confiscate under that name a railway train which had killed a man by misadventure. The foregoing is sufficient to explain the interest of the early coroner in the dead body, for it was always a possible source of revenue.

As the centuries passed, the office of coroner declined in prestige, all his important duties fell away from him, and only the power of holding inquests on dead bodies remained. The office, however, preserved its vitality and with the extension of colonies of Englishmen to other parts of the world, the institution of coroner was transferred with them and to this day is found in the British Commonwealths and in most of the States of the American Union. Both in England and in the other countries the coroner, modified more or less from his prototype of medieval times, still exercises the same function of determining the cause of death by virtue of a judicial process which functions, in many cases, unhampered by any contribution from the science of medicine.

The coroner in most parts of the United States is a county official elected by popular vote for a term of office which varies from two to four years. Ordinarily he is not required to be a lawyer or a doctor, and the only qualification necessary is that he should be eligible for a place on the ticket of the predominant political party. Some states, like Louisiana, have laws which stipulate that the coroner should be a graduate of a medical school and be licensed to practice in the state. In any event, the office is a minor judicial one and in many cases is under the thumb of the local political machine. It is usually compelled to work with insufficient funds, so that it would be incapable of improvement even if the incumbent were impelled by a sincere desire for reform.

When the coroner receives notification of a suspicious death in his jurisdiction, he or his representative visits the scene of death, inquires

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 9, 1944.

From the Office of the Chief Medical Examiner in the City of New York.

into the circumstances, and decides whether to release the body after a mere examination or to hold an autopsy and an inquest. The inquest is a court hearing held before a jury or by the coroner as a magistrate without a jury. Testimony is taken under oath, and at the end of the hearing, either the jury or the coroner decides how death occurred, whether by natural causes, misadventure, suicide, or homicide. Medical testimony may be taken or the report of the autopsy may be introduced into the record, but the coroner has the discretionary power to disregard such evidence. As the result of testimony given in his court the coroner can order the arrest of any person or persons implicated in a homicide and hold them for the higher courts.

The above statement is, of course, an oversimplified description of the coroner system, for in some localities there are officials known as coroners who do not perform their duties in the way I have outlined. It is not my intention to inflict unjust criticism upon those who are worthy or even to indict particular coroners' offices in detail, but I do wish to bring the underlying principle of the coroner system up for a searching examination. The theory upon which the institution of the coroner is based is fallacious; namely, that a local magistrate, usually blessed with doubtful qualifications for his duties, can direct the medical investigation, conduct a judicial inquiry, and in the end determine the cause of death in a given case. The determination of the cause of death is a medical problem and should be the concern of the medical profession. It is only in comparatively recent times that the coroner has sought medical aid for this purpose, and even then he can disregard it. As an instrument for determining the cause of death the coroner's inquest cannot be regarded as efficient.

Is there anything to be said in favor of the coroner system? No, not as it is constituted at present. The poor quality of the typical coroner's office and the misdirected aim of the inquest can be abolished without causing an undue sense of loss. There is, however, an argument for the establishment of the office of magistrate who has investigative as well as judicial functions and can carry his duties to the scene of a crime, where he can gather evidence at first hand. He would not have any control over the medical investigation, but would confine his energies to sifting the other evidence. Such an official would be similar to the procurator fiscal in Scotland or the magistrates in the Republic of Panama. It should be noted that those communities which have adopted the medical examiner system have placed the judicial powers of the coroner in a magistrate.

### Medical Examiner System

The character of this system can be best appreciated by considering its historic development. Its prototype is to be found in the Roman Empire of antiquity, where the *archiatri populares* were official physicians appointed by the emperor for certain districts, principally to treat the indigent sick. There is not any record to indicate that these physicians had any medicolegal functions.

A lineal development from the ancient *archiatri* were the town physicians in Europe during the Middle Ages, who served the community as medical practitioners, army surgeons, police doctors, and medicolegal experts. In the statute laws of the northern Italian republics from the thirteenth to the sixteenth centuries, there are qualifications specified for physicians who were to be considered expert in legal medicine. The principal duties of such experts were the visual inspection of wounds on the living and dead body and the reporting to the authorities as to whether these wounds were mortal or not. Autopsies, however, were not performed in fatal cases of this type. They also investigated suspected cases of poisoning, examined psychopathic individuals, and gave testimony in the criminal and civil courts. There is not any indication that they performed any autopsies as a part of their official duties. Here the true beginning of a medicolegal system makes its appearance, for here the state recognizes the value of medical knowledge for the law.

The "*Constitutio Criminalis Carolina*," promulgated by the Emperor Charles V, appeared in 1530, and increased the importance of legal medicine by announcing that medical evidence must be produced as part of the proof in criminal court actions involving cases of infanticide, abortion, fatal wounds, poisonings, and similar conditions. The statute did not stipulate, however, that an autopsy should be performed on the dead body of the victim of such crimes. In 1562 Ambroise Paré made what was probably the first judicial autopsy and at the end of the sixteenth century the autopsy in medicolegal cases became general. With the increasing complexity of European civilization in the nineteenth century, the authorities were forced to improve the administration of legal medicine and this led to the rise of medicolegal institutes all over the continent in the larger centers of population.

The system in the modern European cities is based on the theory that the police and the judiciary investigate the circumstances of death in all criminal cases, and then send the body to the institute for autopsy. Cases of death not in this category are disposed of through other channels. The medicolegal experts rarely visit the scene

where the body was found, and are mainly responsible for the performance of the autopsy along with such chemical and microscopic examinations as may be necessary to establish the cause of death. In addition, the medicolegal institutes are occupied with a number of diverse activities, such as: (1) interpretation of laws regulating the practice of medicine; (2) psychiatric examinations of individuals involved in court procedures where mental sanity is a point at issue; (3) examination of individuals whose claims for state insurance are disputed; (4) alcohol determinations on the blood and urine of individuals involved in traffic accidents; (5) blood-group examinations in paternity cases; and (6) police-laboratory examinations. Such heterogeneous pursuits are a heritage from the days when medicolegal science was less complex and experts assumed all the tasks allotted them, but at present they must be an administrative headache to the head of the institute.

The present method of medicolegal investigation in Scotland deserves a brief description, for it is derived from France and has no similarity to the coroner system in England. Each district in Scotland is served by a magistrate called the procurator fiscal, who has the duty of investigating suspicious and violent deaths. He visits the scene and has the power of calling in the police and directing their activities, and of summoning witnesses and taking their testimony. If the case seems to be homicidal, he can call in two physicians to examine the body and to perform an autopsy after the proper authorization is obtained. His final report is submitted to the Crown Office of Scotland for disposal.

The medical examiner systems in the United States were adopted in a few states and counties after these communities had rid themselves of their inadequate coroner systems. Massachusetts instituted her medical examiners in 1877 and New York City established the Office of the Chief Medical Examiner in 1918. These systems have this in common with the European medicolegal institutes: that they recognize that the cause of death in any case under investigation must be determined by a medical man, but they differ in two important respects from the European organizations. The first difference is that the American medical examiners visit the scene of death and begin their investigations there, so that the chance of losing important medical evidence is somewhat reduced. The second difference is that they are principally concerned with finding the cause of death, and they are not bothered with the miscellaneous activities which trouble the European institutes. The medical examiner systems in this country are based either on the Massachusetts model or on the one oper-

ating in New York City, and since these differ in some important respects, I will discuss them in greater detail.

The Massachusetts medical examiners are appointed by the Governor with the advice and consent of the Council for terms of seven years, to serve in certain districts. They investigate all deaths which are supposed to have occurred from violence and perform autopsies on being authorized by the district attorney, mayor, or selectmen of the district. Without such consent the medical examiner issues his death certificate only after a simple external examination of the body. Provision is also made for all necessary chemical examinations.

The Massachusetts medical examiner system is open to several criticisms. The first is implicit in the method of appointment of the medical examiners, which is practically under the control of the Governor, and he is not compelled by any provision in the law to select the best-qualified person to fill the position. Second, the individual medical examiners perform their duties in such a way that they rarely come in contact with other medical examiners and so are deprived of mutual aid and criticism. The third and most serious disadvantage of the system is the power of the district attorney to decide whether or not the medical examiner shall perform an autopsy in any particular case. Unless the prosecutor is a man of wide experience, he would not always realize that some types of homicide cannot be detected without an autopsy, and that in refusing to allow one he might create difficulties for the work of his own office. The same criticism can be urged with equal applicability against the medicolegal systems of Scotland and the continent of Europe, where the legal authorities can, to a certain extent, direct the medical investigation.

The organization of the Office of the Chief Medical Examiner in the City of New York is quite different. The Chief Medical Examiner is the head of the Office and he is appointed by the Mayor from the classified Municipal Civil Service list. The Chief is enjoined to appoint qualified deputy and assistant medical examiners and other employees from such Civil Service Lists as may be provided. The law stipulates that the chief medical examiner is to be a "skilled pathologist and microscopist" and that the medical examiners on his staff are to have the same qualifications. The essential character of this office is that it carries on its duties as an organization which is under the direction of a responsible head.

When the individual medical examiner is notified of a case which requires his attention, he goes to the scene where the body was found and starts his investigation. The cases with which he is concerned are those of victims who have

died as a result of criminal violence, of suicide, of casualty, or suddenly while in apparent health, or when unattended by a physician, or in prison, or in any suspicious or unusual manner. The examiner inquires into the circumstances of death, looks over the body, and then may issue a certificate of death if he believes that the cause of death can be determined beyond a reasonable doubt and that the case is not a suspicious one. If he is of the opinion that an autopsy is necessary, he or some other medical examiner performs an autopsy. The autopsy findings are written up in the form of a report and are filed with the rest of the record. Chemical, microscopic, and bacteriologic examinations are also carried out, if the circumstances of the case make them necessary.

As far as the individual medical examiner is concerned, he is made sole judge of how he shall conduct his investigation in determining the cause of death, which means, specifically, whether or not an autopsy shall be performed in the case under consideration. The success or failure of the New York type of the medical examiner system depends overwhelmingly on the qualities of this individual medical examiner. He must be a doctor of high professional ability and unquestioned integrity, otherwise the work of the office will suffer in its quality.

As far as the actual results achieved by the New York City system, it can be said that it has worked satisfactorily in New York and in Essex County, New Jersey. The system is not perfect, but perhaps may be called less imperfect than other systems. Its basic principle indicates the proper goal at which all medicolegal organizations must aim in order to give the best service to the public, and in the future the most successful medical-examiner system will probably be patterned after this model.

## Discussion

Dr. Floyd M. Winslow, Rochester—Two systems of investigating sudden and violent deaths are in use in New York State at the present time; one is the system of investigation by a coroner who is an elected official; the other, investigation by a medical examiner appointed by a city government. The

medical examiner system prevails in a few large cities of the state, while the coroner system exists throughout the rest of the counties of the state. The medical examiner system is a modern development in this field and has existed in this state for the past twenty-six years.

The law which governs the function of a coroner in this state is unsatisfactory because it is vague and loosely written; if one desires to know the law which governs the actions of the coroner he must carefully search the *Civil Code*, finding references to the office of coroner in many different sections of the *Code* with no complete outline of the powers and duties of the coroner in any one chapter. Occasionally legal action is brought for an unauthorized autopsy, sometime later followed by an additional legislative enactment applying to the issue involved. This group of enactments then becomes the law governing the coroners of the State.

While the introduction of the medical-examiner system in some of the larger cities of the state, beginning in 1918, is a modern development in the conduct of this office, there is always a tendency to failure to keep abreast of the times in the laws which govern this office in the state of New York.

The principal objections to the coroner system in this state are:

1. A tendency to political control of the elected coroner and his staff.

2. Inadequate and antiquated methods of conducting the work of the coroner's office. While the larger cities of the state are called upon to provide adequate facilities for the medical examiner to handle the large bulk of this work, the less frequent

It is desirable that every county of this state have the services of a competent medical examiner with adequate laboratory facilities for carrying on incidental serologic, bacteriologic, histologic, and toxicologic investigations.

In consideration of the successful conduct of the medical examiner system in some of the cities throughout the state for the past few years and conversely in consideration of the necessity of improving the functioning of the coroner system as used throughout the rest of the state it would seem that the time has come when a thorough state-wide survey is in order for the purpose of arranging a more satisfactory method of investigating suspicious and violent deaths throughout the State.

## COMMITTEE ON MEDICAL RESEARCH BEGINS PUBLICATION

The Committee on Medical Research of the Office of Scientific Research and Development has recently begun publication of a weekly journal entitled *Summary of Reports Received by the Committee on Medical Research*. Circulation of the publication is restricted to selected Medical Corpsmen in the United States, Canada, and Great Britain. The journal is being edited and published

by the Records Section of the Committee, the work of which is directed by Dr. Kenneth B. Turner, who is on leave of absence from the College of Physicians and Surgeons, Columbia University. Dr. Turner is assistant professor of medicine and assisting physician to the Presbyterian Hospital.—*Released from the Office of the Surgeon General, August 8, 1944*

# AN INTRADERMAL REACTION AS AN AID IN THE DIAGNOSIS OF GRANULOMA INGUINALE

BORRIS A. KORNBILTH, M.D., F.A.C.S., New York City

A TISSUE antigen was prepared from an acute lesion of granuloma inguinale of six weeks' duration in which Donovan bodies were especially numerous and easily demonstrable on smear with Wright's stain (Fig. 1A). The extensive distribution of Donovan bodies in the resected specimen was easily demonstrated in paraffin tissue section stained by the Giemsa method.

The test material was prepared in the following manner: A fair-sized piece of tissue was removed and triturated in a small amount of normal saline in a sterile mortar. The triturated material was diluted so that it would be possible to aspirate it through a 26-gauge needle. It was then bottled and heated at 60 C. for two hours on one day and left in the icebox overnight. It was heated at 60 C. for one hour on the following day. After this procedure, the material was tested for sterility both aerobically and anaerobically and was found to be sterile. Smears showed no organisms or Donovan bodies. They did show amorphous, pink-staining debris. It must be noted that this material was not filtered. It is quite certain that the tissue was originally contaminated with organisms present upon the skin—staphylococci and streptococci. These organisms did not interfere with the quality or effectiveness of the antigen. The manner of preparation is similar to that used in making Frei antigen for lymphogranuloma venereum.

A series of 19 proved cases of granuloma inguinale and another series of control cases were injected intradermally with 0.1 cc. of this test material and the results were observed in forty-eight hours. A negative result showed no evidence of reaction in the skin. A positive result consisted of a tender nodule; an infiltration about 5 to 8 mm. in diameter, surrounded by an erythematous halo of varying size.

The results of these tests are shown in Charts I and II.

The explanation of the "false negative" or "false positive" tests requires further study.

## Histopathology of the Granuloma Inguinale Intradermal Reaction

An oval portion of skin containing a positive intradermal reaction was excised three days after

injection of the test material into a definitely proved case of granuloma inguinale. Sections were stained with hematoxylin-eosin and Giemsa. The microscopic study was made by Dr. Sadao Otani. The essential picture was that of a diffuse epithelioid cell reaction. Epithelioid cells were present diffusely throughout the corium. They assumed a characteristic pattern and were arranged in spheres of varying sizes. The characteristic feature was that of an epithelioid nodule or sphere. The periphery consisted of more compactly arranged layers of epithelioid cells, while the centers were made up of an interlacing, more loosely arranged network of epithelioid cells. Within these clusters there were a moderate number of lymphocytes and plasma cells. There was no evidence of acute inflammation. The reaction was conspicuous because of the absence of polymorphonuclear leukocytes. There was no evidence of necrosis (Fig. 2A). Some giant cells were present (Fig. 2B). Donovan bodies were not found in the intradermal reaction.

A review of the sections of tissue taken from an acute lesion of granuloma inguinale, containing numerous Donovan bodies in the monocytes, revealed similar epithelioid structures in places. These structures were modified by the presence of acute inflammatory changes as a result of secondary infection. The epithelioid structure was obscured by an exudate consisting of polymorphonuclear leukocytes, lymphocytes, and plasma cells (Fig. 1B); giant cells and fresh granulation tissue were likewise present.

It is important to observe that the descriptions of the histopathology of granuloma inguinale, up to the present, are consistent with a description of nonspecific inflammation due to secondary infection with contaminating organisms which accompany these open lesions. The histologic reaction as seen in the intradermal tests is uncontaminated and gave a lead to a similar picture in the original granuloma inguinale lesions. There is thus present a histopathologic correlation between the actual lesions and the confirmatory skin test of granuloma inguinale.

An analogous correlation was shown to exist in the case of lymphogranuloma venereum between the histology of the Frei test and the histopathology of the lymph nodes.\*

rence followed no pattern, being scattered throughout the various ages. They were mostly found in those cases showing marked changes in either the coronaries or in the aortas, though this was not necessarily true.

The severity of the diabetes was very difficult to determine. Over one-third of the patients were brought into the hospital in a comatose state and many died without regaining consciousness. A number presented language difficulties and a number were mentally irresponsible. Again, so many had associated severe infections that our estimation of the tolerance would be unreliable. Nevertheless, of the 45 patients there were 20 who either gave a history of mild diabetes or were proved to have mild diabetes in the hospital. There were 4 who gave a history of moderate diabetes and one who had severe diabetes but had been well balanced for five years, taking between 80 and 90 units of protamine zinc insulin per day.

There seemed to be no relationship between the mild cases and the degree of involvement of the arteriosclerosis. The patients exhibited an almost equal number of normal, moderate, and severe cases regardless of age.

## Discussion

Arteriosclerosis is still the unknown. The cause of this widespread and serious vascular disease is as yet one of the mysteries of medicine.

Because diabetes is the only known abnormality in the body that has any practical influence on the progress of the sclerotic changes in the arteries, we look to students of diabetes for some light on the subject.

While there is ample evidence at hand to show that diabetes speeds up the progress of arteriosclerosis, its full role is not understood. It is generally conceded that it increases the total amount of sclerosis in the arteries of those over 40 years of age, increases the severity of the sclerosis, increases the danger of occlusive accidents, and adds ten years to the individual's actual age. We have recently confirmed these observations in a series of 193 autopsies on diabetics and 2,250 on nondiabetics.<sup>1</sup>

Every patient with diabetes, however, does not develop arteriosclerosis. Warren<sup>2</sup> reports he has collected 13 cases that were free of any changes at postmortem examination. Out of 193 diabetics coming to autopsy we found 28 that gave no evidence of sclerosis. Warren and Root thought that the excessive sclerosis in the diabetic was related to the duration of the disease. Warren in 1930<sup>3</sup> said that he had never seen a diabetic of five years' duration who was free from arteriosclerosis at autopsy, regardless of age. In his 1938 edition<sup>2</sup> he modified this statement by saying that he had since found four exceptions. We noted 7 cases with durations of five or more years without involvement,

and in addition there were 4 more that presented only moderate changes at one of the three points. Root<sup>4</sup> concluded after a study of the aortas in cases of less than one year's duration that there was little difference in the involvement of the diabetic and the nondiabetic of similar age. Yet in those cases of diabetes of long duration he noted much greater severity than in nondiabetics of the same age. It impressed him that the duration of the diabetes regulated the degree of changes in the aorta. Again<sup>5</sup> he was influenced by the extreme degree of changes in a group of diabetics 70 years old or over with diabetes of long duration.

Of course, as is frequently pointed out, diabetes is a disease largely of later life. It parallels, therefore, the onset of arteriosclerosis. We accept the fact that arteriosclerosis is the accompaniment of age in the general populace and that it increases with each succeeding decade. This makes age a pronounced factor and one that must be considered in any appraisal of arteriosclerosis.

There are, however, as shown by Ophuls,<sup>6</sup> individuals dying in every decade up through the nineties who fail to show arteriosclerosis at postmortem. Hence, age cannot be considered a positive factor in the production of sclerotic arteries.

As we have shown, patients with diabetes of reasonable duration may escape arteriosclerosis even though they are of the age in which it is

admittedly active. Such cases are resistant to the combined action of two recognized factors. They must have an inherent resistance to these factors or some antisclerotic factor is in evidence. It is suggestive that the nondiabetics who are resistant to the age factor may be resistant as well to the diabetic factor.

Because all three of our patients under 30 years of age were free from changes, we feel that the duration of the diabetes is not an important factor in youth. This parallels the generally accepted finding that arteriosclerosis is rare in the first few decades in the nondiabetic.

Our data regarding the severity of the diabetes are inconclusive, but the fact that the patients with severe cases might have little change in the arteries and the mild ones severe changes has led us to the conclusion that the degree of the diabetes is immaterial in the progress of the sclerosis.

### Conclusions

1. Arteriosclerosis is a very common though not a consistent finding in cases of diabetes of five or more years' duration.

2. Diabetes of long duration is not a positive factor in the production of arteriosclerotic changes.

3. Age is not a positive factor in the production of arteriosclerotic changes.

4. The combined action of the diabetic and

the age factors does not necessarily produce arteriosclerosis, even in cases of long duration.

5. It is possible that those individuals that are resistant to the age factor are likewise resistant to the diabetic factor.

6. The diabetic factor has less effect on the arteries in youth than in later decades.

7. The severity of the diabetes seems to be of no importance in the stimulation of arteriosclerosis.

## AN OPEN LETTER

To: Lt. (j.g.) Marshall Dann, U.S.N.,  
Former Sports Writer—*Detroit Free Press*,  
Somewhere in the Pacific.

Dear Marshall:

We thought we would write you an open letter to let you know about the latest extra edition out of Washington. A senate committee has just been told that the American Youth (that includes you) are "soft and flabby." We always thought there was something wrong with you.

As we remember, they rejected you first because you had high blood pressure. Well, we proved them wrong on that one. What normal boy's blood pressure wouldn't rise standing around with a bunch of white, black, and yellow youths in the nude in an ex-American Lady Corsét factory. But we did find a hernia the Army had overlooked so they turned you down for that the next time. Well they couldn't do that to you so you had an operation. By some miracle, those soft and flabby muscles held and four months later you were in the Navy. We don't know what the Navy did with that softness and flabbiness but the last we heard of you, you were piloting boats bringing up food to our fighting men on the islands in the South Pacific with as much energy as you used to use hunting good grub in this burg of ours. All this showed the manliness and courage typical of American youth and you were only one of thousands who had similar experiences. Just soft and flabby guys.

Now Marshall, you know the American youth. You were no great guns as an athlete (except for a lousy game at golf) but at Michigan State you were a special reporter for the *Free Press*. You knew the athletes and the student bodies at State and the U. of M. and you met college teams from all over the country. Weren't those fellows a bunch of pansies? So soft and flabby with a skin you loved to touch but you had to be careful there was no static spark in that touch or it might set off some dynamite. Then you came down to Detroit as sports writer for the *Free Press* and, as such, covered the high school and sandlot sports. Those Cooley and Catholic Central football teams were a bunch of cream puffs. Those Firemen Midget baseball teams were puny little devils. And those track and basketball boys certainly showed off their malnutrition in those skimpy suits. But they played the game and took the bumps and didn't shed any tears except in the chagrin of defeat—soft and flabby.

Sure, they say these were the athletes. But how would you have liked to risk your neck by calling the U. of D. High rooters a bunch of dirty Irish or the Hamtramck rooters skunks or the Western

rooters river rats and so on down the line. Even though they got their grade-school physical training under a skinny-legged, bespectacled female gym director, they could still stand up for their rights and their softness and flabbiness wouldn't have been much help to you if you incited them.

You bet those kids were soft and flabby. They'd thumb a ride for two blocks to get a field to play all afternoon. In place of tough muscle-bound bodies, they had brains and ingenuity. Even some of those turned down as neurotics outsmarted the psychiatrist. While the rest of the world hiked, they went for a ride in a shiny automobile. They had brains and ingenuity along with their softness and flabbiness. Every 14-year-old had the coordination of eyes, ears, mind, and soft and flabby muscle that could take the old bus down the road at 60 or 80 miles an hour. They knew no fear. Besides, if that auto didn't move, they could take it apart and find out why. Why work if you can get someone else or a machine to do it for you? That is soft and flabby.

Why walk if you can ride? Remember the year State played in the Orange Bowl and you didn't have the dough to get to Miami? Did you start walking? No, you thumbed a ride both ways, had a swell trip, and came back to Lansing with more money in your pocket than when you started. Your soft and flabby muscles didn't get you there but your brains and ingenuity and personality did. Just another typical trick of our soft and flabby American youth.

Now, most of those boys you knew or wrote about are in the military service and most of them volunteered and didn't wait for the draft. A few weeks of military training toughened up the soft and flabby body. But the American youth didn't take Sicily, Normandy, Guadalcanal, Tarawa, or Saipan with their bodies alone. They used their brains and ingenuity. One can train soft and flabby muscles in a few weeks but it takes years to train a mind. You have seen them in action, Marshall, so you know.

Col. Rowntree can have the regimented goose-stepping German, the bespectacled Jap, or the sundried Italian but you and I will put our money on that soft and flabby guy we call the American youth.

Well, Marshall, you're in the Navy and I know you can't answer this until the duration is over. Just give those Tojo's hell for us poor 4F's at home and take care of a good, game guy named Marshall. When another extra comes out from Washington, we will let you know the *Bull*.

Sincerely yours,  
W. B. Harm, M.D.,—*In Detroit*

## MODERN TREATMENT OF VARICOSE VEINS

With Special Reference to the Use of Sylناسol\* as a Sclerosing Agent

WILLIAM M. COOPER, M.D., F.A.C.S., New York City

THE literature of the past decade with respect to the use of the salts of the fatty acids in the obliterative treatment of varicose veins, is voluminous. This paper details my experience with sylناسol in the sclerosing treatment of varicose veins during the past five years, both in my clinic at the New York Polyclinic Medical School and Hospital and in private practice.

Sylناسol is a 5 per cent solution of the sodium salt of the fatty acids of a vegetable oil extracted from the seed of the psyllium group. I have used it alone or following preliminary high ligation and division of the saphenous veins when such an operation is indicated. The indications for preliminary high ligation and division of the saphenous vein, or veins, are given in detail below.

No attempt will be made to give statistical tables, since the writer is primarily interested in the practical clinical application of the material used in this study. The observations and conclusions are based upon results obtained in a large clinic and practice.

In a paper<sup>1</sup> published in the *American Journal of Surgery* in 1933, I discussed the action and uses of sodium morrhuate and, at the same time, described certain reactions which, while not serious, occasionally caused discomfort to the patient and some alarm to the physician. On the other hand, the action of sylناسol was found to be constant and predictable with but rare exceptions.

### Direction of the Blood Flow in Varicose Veins—The Trendelenburg Test and the Perthes' Test

In 1934 I<sup>2</sup> pointed out that in order to treat varicose veins successfully, it is necessary to fully understand the principles of the normal venous flow and the alterations which occur in the varicose state. The Trendelenburg phenomenon or test when properly performed, gives precise information regarding valve function and the presence or absence of reverse or backflow from the deep into the superficial veins. The four Trendelenburg states, according to Berntsen,<sup>3</sup> are shown in Fig. 1.

In accordance with this test, varicose veins

are classified as Trendelenburg positive, negative, double or doubly positive, and nil.

**Trendelenburg Test**—The patient stands with both lower limbs exposed to the groin. All the superficial veins are inspected and palpated to ascertain their size and the degree of tension or pressure within the vein. The patient is then placed in a recumbent position, the leg is elevated above the level of the pelvis, and the veins are stroked or "milked" toward the groin, thus emptying them. A tourniquet is placed around the upper thigh with sufficient pressure to block the superficial veins. The patient stands, and the veins below the tourniquet may remain collapsed and then fill slowly from below upwards in thirty-five to sixty seconds, or longer in some cases. The test is repeated, and when the patient stands the tourniquet is released quickly. If the veins distend quickly from above downward to their former state of tension, the patient is classified as *Trendelenburg-positive*.

The Trendelenburg-positive group comprises those cases in which the valve function in the upper part of the great saphenous vein is deficient or absent, permitting reverse flow from the femoral vein into the saphenous vein at the saphenofemoral junction. This is the type of case most frequently encountered and it is most effectively treated by preliminary high ligation and division of the great saphenous vein, and separate ligation and division of all the tributaries at the fossa ovalis, with subsequent injection therapy.

The immediate benefits to be derived from a high ligation and division of the great saphenous vein can be demonstrated visibly by the Trendelenburg test, what the tourniquet accomplishes

Fig. 1 The four Trendelenburg states

Adjunct professor of surgery, assistant attending surgeon and Director, Department of Peripheral Vascular Diseases, New York Polyclinic Medical School and Hospital.

\* The sylناسol used in this study was furnished through the courtesy of G. D. Searle and Company, Chicago, Illinois.

in preventing backflow in a valveless vein is precisely what the operation will do. So many surgeons<sup>4-14</sup> in recent years have adopted this type of surgery that there can be little doubt of its efficacy.

According to DeTakats,<sup>15</sup> the pressure in a valveless great saphenous vein when the patient is standing may be as high as 210 cm. of water. Obviously, high ligation as a preliminary measure in this type of case is the only means whereby this tremendous pressure or backflow can be prevented.

The *Trendelenburg-negative* case is one in which reverse flow from the deep veins into the superficial veins takes place through one or more dilated communicating veins, described by McPheeters<sup>16</sup> as "blowouts." On performing the Trendelenburg test in this group, the veins will fill rapidly when the patient stands with the tourniquet pressure maintained. If the varices in the leg are very large, preliminary ligation or ligations should be performed at the highest demonstrable point of backflow and all other points of reverse flow below it. In such cases I usually perform a high ligation and division of the great saphenous vein as an added measure of security. The sources of backflow from the deep veins may be more accurately ascertained by a modification<sup>17,18</sup> of the Trendelenburg test, or by the stripping method of Ochsner.<sup>19</sup>

The *Trendelenburg-double* group comprises those cases in which the backflow takes place at the saphenofemoral junction as well as through one or more of the dilated communicating veins in the lower part of the limb. Briefly, it is a combination of the positive and negative types of backflow and the treatment obviously is high ligation and division of the great saphenous vein, and ligation or ligations in the lower part of the limb wherever backflow can be demonstrated. This group makes up only a small percentage of the cases encountered in practice.

*Trendelenburg nil* cases are those with dilated veins in the presence of competent or normal valves. This is the early type of case frequently seen with no reverse flow. These varices may be obliterated by simple sclerosing injections.

## Summary of Trendelenburg Test

### Positive:

- A. With tourniquet on—veins fill slowly from below upward (35 to 60 seconds).
- B. With tourniquet off—veins fill quickly from above downward (1 to 10 seconds).

### Negative:

- A. With tourniquet on—veins fill quickly.
- B. With tourniquet off—veins fill quickly.

### Double:

With tourniquet on—veins fill quickly below the tourniquet but become fuller, or more tense, when the tourniquet is removed.

### Nil:

- A. With tourniquet on—veins fill slowly.
- B. With tourniquet off—veins fill slowly.

In performing the Trendelenburg test, the status of the short saphenous vein must also be borne in mind. One frequently sees cases in which reverse or backflow takes place from the popliteal vein into the short saphenous vein at the popliteal fossa. In such cases the same principle of treatment is applied—namely, high ligation and division of the short saphenous vein at its junction with the popliteal vein.

The *Perthes' test*, or Perthes' modification of the Trendelenburg test, is a simple test to determine patency of the deep veins. Theoretically, it should be performed on every new case before commencing treatment, operative or otherwise. In the absence of any edema or previous thrombophlebitis, however, it is safe to state that one may proceed with treatment without performing the test. Apply a tourniquet above the knee with sufficient pressure to block the superficial veins only, while the patient stands and the veins are distended. The patient is instructed to walk about actively. If, with the tourniquet in place, the veins below it collapse (empty), then one may be certain that there is no serious deep vein blockage and the patient may be treated. On the other hand, if the veins become more tense and cause pain, deep venous occlusion must be suspected and conservative treatment should be given. This test may be performed with a tight elastic bandage applied to the limb to be tested from the toes to the knee or above it.

Recently several workers have reported treating varicosities of patients with a history of thrombophlebitis if the acute process had occurred a number of years previously and Nature has had an opportunity to establish an adequate collateral circulation in the deep venous system. This attitude seems reasonable, since it is well understood that varicose veins are derelict veins, permitting reverse flow and in no conceivable manner functioning as normal veins in returning blood to the heart. The presence of edema and enlargement of a limb should make one suspicious of an insufficient deep vein circulation and great caution must be exercised before treating such patients. In the absence of edema, however, it is safe to assume that the deep veins are patent and functioning well, and to proceed with treatment in such cases. The constant application of the Perthes' test, or one of its modifications,

should give one experience in eliminating those cases not suitable for sclerosing therapy. In this connection the value of phlebography should not be overlooked. This method of diagnosis has been used rather too seldom.

### Indications and Contraindications

Much confusion exists in the minds of physicians regarding the indications and contraindications for sclerosing therapy. Numerous papers<sup>20-22</sup> have appeared in the past decade, some of which list every known acute illness, while others, interested in the mechanics of the blood flow, list the local conditions which logically are contraindications to the injection treatment.

In 1935, Edwards<sup>22</sup> in his paper "The Treatment of Varicose Veins: Is Systemic Disease a Contraindication?" discusses his experiences in a large city hospital clinic in Boston where, in a series of 1,000 consecutive patients, only three reactions were noted and these, fortunately, were not serious. It must be remembered that Edwards' experience embraced the type of patients usually seen in a city hospital clinic, with chronic disease as a background. Strictly speaking, on the basis of generally accepted contraindications, 375, or 37.5 per cent of the reported series, might have been denied this beneficial injection therapy.

For a detailed discussion of this topic one is referred to the excellent treatises of McPheeters<sup>23</sup> and Edwards.<sup>22</sup> In short, however, it might be stated that the injection of sclerosing solutions into varicose veins is indicated in all cases of varicose veins and conditions secondary to or resulting from varicose veins, providing no serious contraindication to such therapy exists.

For practical purposes the contraindications to injection therapy may be briefly summarized as follows:

1. Local causes
2. General diseases

The local causes which, in my opinion, definitely contraindicate injection therapy are diseases of the peripheral circulatory apparatus such as Raynaud's syndrome, thromboangitis obliterans, and advanced peripheral arteriosclerosis, whether due to diabetes or other causes, acute, subacute, and chronic thrombophlebitis of the deep veins with manifest impairment of function of the deep venous system, and acute superficial thrombophlebitis. Elephantiasis is listed by numerous writers as a definite contraindication. Pelvic tumors and inflammations are among the local conditions which contraindicate sclerosing therapy, and such treatment may be deferred until the underlying pathologic

pelvic condition is corrected. If the varicose veins then persist, injection therapy and/or operative correction is in order, whichever may be indicated.

Among the general causes may be mentioned uncontrolled diabetes, untreated syphilis, active tuberculosis, acute or latent thyroid disease, nephritis, malignancy, severe cardiac conditions including coronary disease, and general debility. As a matter of fact, one may go through the whole gamut of medical conditions or diseases and cite them as contraindications! For the sake of brevity, one can state that injection therapy should not be given in the presence of any acute or serious chronic illness, since the treatment of varicose veins is largely elective.

The presence of large ulcerations *per se*, when manifestly infected, as all varicose ulcers tend to be, might be considered a contraindication to injection therapy. In such cases, if the veins are large and the Trendelenburg test proves them to be of a type amenable to the operation of high ligation and division of the saphenous vein, I usually defer injection therapy but do not hesitate to operate at once. I believe that ulcers associated with large varicosities are a valid indication for the operation in the same sense that acute superficial thrombophlebitis calls for early operation. The quick response of ulcers associated with large varicosities after ligation and division of the affected vein is sometimes astounding.

There seems to be considerable difference of opinion not only among physicians but in the minds of the laity regarding the problem of thrombophlebitis. Since my experience embraces well over 300 cases of acute superficial thrombophlebitis involving either the great saphenous or short saphenous veins operated upon with not one untoward result, there is no doubt in my mind of the value of this procedure in such cases. For a more complete discussion of this subject, the reader is referred to the excellent work of Homans,<sup>24</sup> Welch and Faxon,<sup>25</sup> and others.

In July, 1942, Chapin and Asmussen,<sup>21</sup> of the Massachusetts General Hospital and the Fatigue Laboratory of Harvard University, reported "On the Occurrence of Dyspnea, Dizziness, and Precordial Distress Occasioned by the Pooling of Blood in Varicose Veins." These workers made a careful study of 250 patients afflicted with large varicose veins in the outpatient department of the Massachusetts General Hospital. The surprising result of this was to find that 47 (18 per cent) of the 250 complained of undue shortness of breath that was relieved in the recumbent position; 19 of these 47 also suffered mild precordial pain or palpitation, or

were uncomfortably aware of their heart action, and 3 were women who experienced attacks of sudden dyspnea, dizziness, and precordial pain simply on standing. These 47 patients were without gross signs of the known types of heart disease, although in some the blood pressure was slightly elevated. These authors also pointed out that in patients with large varicose veins it is evident that an amount of blood in excess of 500 cc. accumulates in their veins during standing or walking, and they concluded that undue fatigue, shortness of breath, dizziness, fainting, and precordial distress may be occasioned by the pooling of blood in varicose veins. These clinical investigations offered evidence that the circulatory efficiency is decreased by such extensive pooling and that removal of this peripheral blood reservoir restores the hemodynamics of the subjects toward normal and relieves their symptoms.

Pregnancy, formerly considered a definite contraindication to operative or injection therapy, is not so regarded any longer by most surgeons<sup>32,33</sup> conversant with this type of surgery. I have operated upon 32 gravid women up to the sixth month of pregnancy, and have given injection treatments in a large series of cases at my clinic without incident. Treatment is usually discontinued at the beginning of the eighth month and resumed, if necessary, when the patient is ambulatory postpartum and can come to the clinic or office.

### Technic of Injection

Assuming that the patient has been examined as outlined by the Trendelenburg and Perthes tests and is considered a suitable subject for sclerosing therapy, how does one proceed with treatment?

Those patients who present large varices are treated according to the method of McPheeters,<sup>34</sup> namely, isolation of a segment of vein between tourniquets after the vein has been emptied by elevation of the limb, the patient being recumbent, or by the use of an occluder (McPheeters, Theis). The skin at the site of injection is prepared with a suitable germicidal solution. Most patients are treated while standing, or while sitting on a table or platform about 30 inches high, with the legs in a dependent position. This renders the veins more prominent.

A 5 cc. syringe fitted with a sharp, short-bevel 25-gauge needle is then gently and firmly pushed through the skin into the vein with the needle upward. The position of the needle in the vein is quickly ascertained by the presence of blood which trickles or flows through the needle into the syringe. If the vein is small, the injection is given without further preparation; if medium-

sized or large, the vein is "milked" with the thumb and middle finger of the left hand, or by an assistant, after which the injection is given.

Unlike sodium morrhuate, which is relatively toxic in large quantities, synlasol may be used in amounts ranging from 5 to 10 cc. at one sitting.

I usually inject from 0.5 cc. to 3 cc. of the solution at any one site and, as a rule, place the first injection at the highest point in any vein or group of veins. As soon as the desired quantity of solution is injected, a tonsil sponge moistened with alcohol or a sterile dry sponge is then placed firmly over the site of the puncture and the needle is withdrawn. An adhesive strip about 8 inches long and 1 inch wide is placed over the sponge, binding it firmly over the injected area. The patient is instructed to remove the dressing after twenty-four hours and not to massage or rub the limb at the point injected.

Injections may be repeated at intervals of two to seven days and in no case is a total quantity of more than 10 cc. of the solution injected at one sitting.

All patients presenting extensive varicose vein formations are instructed in the proper application of a spiral elastic bandage which they are requested to wear throughout the treatment and for a short period after its completion.

Treatment may be given as often as three times a week, and if a period longer than two weeks has elapsed between treatments, it is advisable to resume treatment with a smaller quantity of synlasol in order to be certain the patient has not become sensitized. In this connection, one of the earliest and most valuable signs of impending allergy or anaphylaxis is the symptom of itching. Care should be taken to distinguish this itching from that occasionally seen at the site of injection where a local patch of dermatitis may be present as a result of the wet sponge which has been kept in contact with the skin for a day.

### Results

1. Synlasol was injected approximately 25,000 times in about 2,000 patients for the treatment of varicose veins, both in the clinic and in private practice (with the almost complete exclusion of any other sclerosing agent). This treatment was given either without preliminary ligation and division of the affected veins, or after the latter procedure had been carried out in cases of extensive varicosities with demonstrable reverse or backflow.

2. Not a single instance of injection ulcer or sloughing has occurred in this series of cases, nor has a single serious infection or thrombophlebitis

followed its use in the sclerosing treatment of varicose veins.

3. Allergy or sensitization was noted in only 5 cases, and 4 of these occurred in patients who had been treated with synlasol previously but who had had no injections for at least one month prior to the occurrence of this complication. Only one patient suffered a severe anaphylactic reaction (in my office) and this patient recovered after the administration of adrenalin, external heat, and rest. In this connection it might be wise to stress again the importance of itching as a premonitory symptom of impending allergy or anaphylaxis. At this point also it is advisable to stress the importance of testing the new patient, and old patients who have not been treated for some time, with a small injection of approximately  $\frac{1}{2}$  cc. of synlasol before proceeding with larger doses. Should the patient persist in manifesting intolerance of synlasol, it is my practice to stop its use and inject some other unrelated material, such as invert sugar or dextrose and saline, in the further treatment of the patient thus affected.

4. The objectionable symptoms of severe pain and cramp so frequently seen with some of the older solutions has not been encountered by me in any instance when synlasol was used.

5. Massive obliteration of the veins such as occasionally follows the injection of sodium morrhuate rarely occurs with synlasol.

6. Pigmentation, which is frequently seen after the injection of some of the older sclerosing agents, such as sodium salicylate, quinine, hydrochloride and urethane, and sodium morrhuate, is practically never seen when synlasol is used.

### Summary

An extensive trial of synlasol in 2,000 cases over a period of five years leads me to conclude that synlasol fulfills all the requirements for a safe and effective sclerosing agent in the treatment of varicose veins. Its use is attended with

none of the objectionable symptoms (pain, cramps, and systemic reactions) and sequelae (sloughs, residual discoloration, and nodulation) which result from the injection of some of the older sclerosing agents.

### MORTALITY CURVES IN TUBERCULOSIS

The mortality curve in women reaches its high point in the middle of life, and is much higher than in young men, but the knowledge when it is evident that the

one high-rate group into the working and living conditions of another high-rate group; and unless every precaution is taken, the factors which contribute to the high rates in these respective groups may act and react upon each other to the jeopardy of the human beings concerned. Obviously, the situation has within it all the elements of an epidemic (or high endemic) potential.—Ed., *Am. J. Pub. Health*, July, 1943

# SPINAL FLUID FINDINGS IN CASES OF SYPHILIS IN THE GENERAL POPULATIONS OF MALES BETWEEN THE AGES OF 18 AND 38 YEARS, WITHOUT DETECTABLE NEUROLOGIC CHANGES

F. P. GUIDOTTI, Lt. Col., (MC), R. N. CARRIER, Maj., (MC), and W. E. STUMPF, Capt., (MC)

CASES for this study were taken from selectees passing through the Armed Forces Induction Station, 480 Lexington Avenue, New York 17, New York. During the period of this study 218,133 selectees were reviewed. Of this total 5,487 were found to have syphilis. Chart 1 shows the percentage of white and colored selectees going through the station; also, the number having syphilis, with respect to race and the percentage of each race.

Of this group we are reporting spinal fluid findings for 3,000 cases only, because some of the patients were rejected for other reasons and therefore the spinal tap was not necessary to decide their acceptability. A complete history of each man was taken with reference to the onset of the disease, duration, amount of treatment, and results of previous spinal fluid examinations. Minimum adequate treatment was based on 42 intravenous and 18 intramuscular. A history of spinal tap within one year which was negative was accepted.

The first series of 1,500 cases were those of patients who had a history of syphilis for a period of five years or longer or of unknown duration (discovered by routine Wassermans given at Selective Service), or those with physical findings suggesting neurosyphilis. The second series comprises 1,500 examinations done on all syphilitic selectees except those with negative blood Wassermans, adequate treatment, and a history of the spinal fluid being negative.

Cases were classified as to the duration of the disease in years: congenital, one year, two years, three to four years, five to ten years, ten to fifteen years, fifteen to twenty years, twenty years or longer, and unknown duration. Chart 2 is self-explanatory as to duration, blood serologic findings, and treatment.

As may be seen in Chart 2, in duration one-sixth of the cases were of one to four years, and five-sixths were of over five years, or of unknown duration. Approximately two-thirds had positive serology and one-third negative. The majority of patients had received adequate or at least some treatment. Only 353 out of the total of 3,000 patients had not received any treatment. The majority of the cases in which the duration of the disease was unknown were discovered by the local Selective Service boards by routine Wassermans. This was the reason that many of the young men started their treatment. It is evident

that a great amount of good has been done by this simple routine procedure. Practically all of the patients in this series were single men or men who had been married since Pearl Harbor.

In the series of 3,000 spinal taps of syphilitics, 294 were found to have sufficient pathologic changes to cause rejection. These are shown in Chart 3.

Based on the findings in Chart 3, the following types of cases may be classified as latent syphilis:

## Early latent (asymptomatic):

Without detectable clinical signs or symptoms.

Infection of less than four years' duration, with or without treatment. If duration is unknown, patient less than 25 years of age.

Wassermann positive or negative.

## Late latent (asymptomatic):

Without detectable clinical signs or symptoms.

Infection of four or more years' duration, with or without treatment. If duration is unknown, patient 25 or more years of age.

Wassermann positive or negative.

Of the total 294 positive spinal fluids, only 25 were from patients below the age of 25. Of the early latent syphilis patients 15 were below the age of 25. Spinal-fluid changes in untreated early latent syphilis were found to be relatively infrequent. In treated early latent syphilitics, changes were more frequent. Spinal-fluid changes occur with practically the same frequency in late latent syphilis, regardless of the amount of treatment. Seven selectees with positive spinal-fluid findings had received adequate treatment and had a negative blood Wassermann. It is felt that negative blood serology is no indication of spinal fluid findings in any state of syphilis regardless of the amount of treatment.

It is evident, though, from Chart 3 that changes in the spinal fluid are more frequent in latent syphilitics with positive blood Wassermans.

Chart 4 shows the pathologic spinal fluid changes in the 294 selectees rejected.

The percentage of spinal fluid changes leading to rejection was 9.5 per cent, as shown in Chart 3.

CHART 1

	White	Colored	Total
Number of selectees examined	192,895	25,238	218,133
Number of syphilitics	2,776	3,071	5,847
Percentage of syphilitics	1.03	12.16	2.68 (average)

All patients except 15 had positive spinal Wassermanns. The second most persistent finding was increased globulin (174), third in importance was the colloidal gold curve (92). Least change was in the cell count (38).

Chart 5 records 100 cases that showed increased globulin only. These cases were accepted but it is felt now that they are a poor risk.

It is felt by the authors that increase in protein content of the spinal fluid is of utmost impor-

tance and is one of the earliest signs of involvement of the central nervous system in syphilis.

Chart 5 also includes 53 cases that showed change in cell count only (above 4).

### Conclusions

1. A study of spinal fluid findings on 3,000 syphilitics has been presented.

2. Many of these cases were discovered by the routine Wassermann tests given by local Selective Service boards.

3. In 3,000 cases among selectees 9.5 per cent had sufficient cerebral spinal fluid changes to war-

rant rejection by the armed forces.

4. Spinal fluid changes are more frequent in late latent syphilitics with positive blood Wassermanns.

5. Negative blood serology is no indication of spinal fluid findings in any state of syphilis regardless of the amount of treatment.

6. It is felt that changes in globulin content are most important as an early sign of syphilis of the central nervous system.

7. More adequate treatment is to be desired with spinal fluid examinations routinely, during and prior to termination of treatment.

### NURSE RECRUITMENT SLOWED UP

Supporting the plans of the Army and the Red Cross to provide adequate nursing care for wounded soldiers, Paul V. McNutt, Chairman of the War Manpower Commission, has instructed the War Manpower Commission's Procurement and Assignment Service to request hospitals and physicians throughout the country to assist in the recruitment of nurses.

"I am informed that the Army is in need of 4,000 nurses immediately," said Mr. McNutt. "Recruitment of nurses, I am told, has slowed up along with the growing belief that the war in Europe is about over."

"The men wounded in battle must have adequate care. No matter how quickly the war is brought to an end, we still have the problem of taking care of those wounded in recent battles who are now being brought to this country for hospitalization. We expect also that the final battle of Germany will not be without considerable casualties. We do not know how numerous these casualties will be. We hope they will be low, but we must be prepared. Nor does anyone expect a quick end to the war in the Pacific."

"I can think of no greater responsibility for professionally trained nurses than that of volunteering for duty in the care of our wounded soldiers. I hope and trust that all nurses who have been classified as available for military duty will immediately consider such action."

Mr. McNutt said that about 29,300 student nurses are being graduated this year. Of these, about 9,000 are needed for service with the Army or Navy. Out of a class of 26,816 graduated last year, about 4,803 nurses entered the armed forces for nursing service.

Although the larger total of nurses needed for military service would leave a smaller number of graduates this year for civilian nursing, there need be no curtailment of essential home-front nursing service, provided hospitals, physicians, civilians, and nurses themselves cooperate to assure the fullest use of nurses in their professional capacities, Mr. McNutt said he had been informed.

At present there is considerable underuse of the professional services of nurses with the result that

we have "luxury nursing" in some communities and an inadequate supply of essential nursing in others, reports to him indicate, Mr. McNutt said.

Mr. McNutt reported he had been informed that in some cases hospitals and physicians could help increase the supply of nursing services for essential needs by eliminating use of nurses and student nurses in clerical and other nonprofessional work. Civilians, he said, can help by not employing nurses except in cases where patients are critically ill.

Mr. McNutt suggested the following order of nurse use to assure that their services will be available on the highest professional level:

1. Nurses who can be spared from essential civilian services should volunteer for service with the Army or Navy.

2. Nurses who are employed in nonessential work should transfer to essential nursing services.

3. Civilian users of nursing services, including hospitals and physicians and patients, should share available nursing service according to the greatest need.

4. Inactive nurses, especially in outlying communities, should return to duty.

The armed forces, the W.M.C. chairman said, report a slowing down in recruitment of nurses, in spite of critical need, especially in Army and Navy hospitals in this country. Mr. McNutt paid a tribute to the nurses who have left civilian service for duty with the armed forces.

"The heroism," he said, "of our nurses on land and sea matches the courage of our brave soldiers and sailors. Many thousands of gallant fighting men owe their lives to these heroines who have gone to duty far from home. I have been informed that 175 Army nurses have been killed by enemy action or have died as a result of illness or injuries contracted in line of duty since December 7, 1941. They, indeed, have served humanity and the nation owes a debt of gratitude to them."

The W.M.C. chairman pointed out that nurses are classified as available for service with the Army or Navy only if State and local procurement and assignment committees, after studying community nursing needs and services, agree they can be spared.—Release from the Office of War Information

# Case Report

## MULTIPLE MYELOMA IN A FIFTEEN-YEAR-OLD BOY

MICHAEL A. RUBINSTEIN, M.D., New York City

IN SPITE of the ever-increasing number of observations reported of multiple myeloma, clear-cut cases in younger age groups are still extremely rare. Some of the cases reported earlier<sup>1,2</sup> have been subsequently questioned for lack of convincing evidence,<sup>3</sup> while other reports<sup>4</sup> have been altogether discarded as not true myeloma.

In the classical textbooks of medicine and hematology the occurrence of myeloma is stated to be limited almost exclusively to those of older age. In his *Textbook of Blood Diseases* Naegeli records (1931) Klemperer's case of a 27-year-old woman as the youngest patient with myeloma reported. Matthes (1934), in his *Differential Diagnosis*, asserts flatly that multiple myeloma occurs only in the older age groups.

More recently, however, a few patients under the age of 20 have been reported showing highly suggestive or direct evidence of true multiple myeloma. On the other hand, some older patients originally reported under various descriptions have been recognized as having myeloma on subsequent review in the light of new knowledge. For instance, the case described by Nothnagel as lymphadenia ossium in a 24-year-old patient was, most likely, a case of myeloma. The more recent cases have been reported by Slavens,<sup>5</sup> Carlson (1936), Schaffer,<sup>6</sup> Laurentius,<sup>7</sup> Ghornbley and Pollock,<sup>8</sup> Bertrand, *et al*,<sup>9</sup> Williams, *et al*,<sup>10</sup> because of a more detailed account of hematologic, x-ray, and pathologic findings, special attention attaches to the cases published by Zach<sup>11</sup> and by Gordon and Schneider.<sup>12</sup>

The case reported by Zach concerns a 6-year-old boy who, on admission, presented a picture of cervical spondylitis considered to be of tuberculous origin on the grounds of characteristic clinical and x-ray findings. In the terminal stage the picture was complicated by the development of symptoms of cord compression. The diagnosis of multiple myeloma was made only at autopsy when lesions were found in the vertebrae, as well as "pulmonary metastases." No blood or bone-marrow studies were done. The histologic picture given in the pathologic report was not very clear. No plasma cells were found and the lesion was defined as being formed by three different types of cells described as myeloblasts, erythroblasts, and myelocytes.

The case of myeloma in a 9-year-old boy, described by Gordon and Schneider,<sup>12</sup> is very interesting. It was of the plasma-cell type, but presented many atypical features. No gross lesions were apparent in the skeleton. There was no distinct nodular involvement of the skeleton. The case was defined

by the authors as a "diffuse plasma-cell myeloma," and was regarded by them as "somewhat intermediate between true plasma-cell leukemia and plasma-cell myeloma." In this respect it would constitute another link in the chain of plasma-cell tumors. "At one end of this series is the typical multiple myeloma, at the other the rare plasma-cell leukemia, in between occurs a great variety of transitional forms. This case lies close to the extreme represented by plasma cell leukemia. The changes found in the organs suggest that, had the patient survived for a longer period, he might have developed frank leukemia."

Our case is a typical representative of the classic nodular multiple myeloma. It concerns a 15-year-old boy (12 at the onset) who sustained a pathologic fracture of the femur. Originally the diagnosis of osteosarcoma was made on the basis of clinical and x-ray impressions. The study of a sternal marrow aspiration was the first to lead to the diagnosis of multiple myeloma. This diagnosis has been subsequently confirmed by the pathologic examination of biopsy material. Because this case confirms once more in such a striking manner the importance of bone-marrow studies in the diagnosis of multiple myeloma, and because it proves that the possibility of multiple myeloma should always be kept in mind even in young patients, it seemed to us to be worth reporting.

### Case Report

Patient A. W., a 15-year-old boy, was admitted to the Montefiore Hospital on November 30, 1942, having been transferred from another hospital with the diagnosis of "small-cell sarcoma of the upper end of left femur and left side of pelvis with metastases to calvarium."

The patient gave a history of having had pain in the left hip for three years. The pain in the beginning was short and recurrent, and was treated as rheumatism; half a year after the onset of the pain the patient was unable to bear weight on the left leg, because of the severity of the pain.

In June, 1942, while walking in the park, he was attacked and had to be taken to the Fordham Hospital. Fracture of the left hip was found and the leg was placed in traction. On October 8, 1942, he was fitted with a brace and began to walk, but on October 13 he suddenly experienced severe pain in the left lower thigh. Soon afterwards he also developed . . . . . est. The . . . . . hology of the . . . . . s and left . . . . . chondrosarcoma . . . . . of osteoporosis with partial erosion and destruction of the cortex of the lower third of the shaft of the left femur. Small areas of osteoporosis noted over the pubic bone and the acetabulum suggested meta-

stases. There was pathologic fracture of the neck of the left femur with callus formation and partial bone union.

The patient was transferred to the Beth Israel Hospital on October 18, 1942, where a bone biopsy revealed a malignant tumor, reported as probably sarcomatous. X-ray studies showed an extensive destructive lesion in the left hip involving the neck of the femur, the intertrochanteric region, and extending down to the shaft; the x-ray of the skull showed multiple small and large osteolytic metastatic lesions. The patient continued to complain of pain in the chest, but the chest plate was persistently negative. The patient was transferred to the Montefiore Hospital for chronic care.

Physical examination revealed a well-developed, very thin and pale boy of 15, appearing chronically ill. Physical findings were essentially negative except for the abnormalities of the bony skeleton. The left leg was  $1\frac{1}{2}$  inches longer than the right; the upper third of the left femur showed a spindle-like swelling and reddish discoloration of the skin. A hard mass, about ten cm. in diameter, was felt in the upper third of the femur where a well-healed scar was seen. Active mobility of the extremity was greatly restricted.

Two weeks later the patient started to complain of increased pain in the chest and examination revealed a hard, tender swelling 2 inches in diameter, over the sixth rib on the right side.

X-ray studies made on December 12, 1942, revealed a malignant tumor, most likely osteogenic sarcoma; the bone destruction was found to include both trochanters, the upper end of the shaft, and the neck of the left femur. There was a pathologic fracture of the left femur and some bone condensation in the region of the fracture. Skull studies of January 15, 1943, revealed numerous small and large areas of bone destruction throughout all bones of the calvarium; they were reported as metastatic bone lesions.

The x-ray report of February 19, 1943, based on a review of all previous records, suggested the presence of Hand-Schuller-Christian disease. This diagnosis was thought to be substantiated by the marked improvement in the healing of the lesions at the site

FIG 2 Bone destruction in the sixth rib.

of the fracture seen on x-ray examination of February 11, 1943, which showed a considerable amount of new bone formation.

Laboratory findings were reported as follows:

November 30, 1942, hemoglobin, 70 per cent; red blood cells, 4,660,000; white blood cells, 5,700; nonsegmented neutrophils, 3 per cent; segmented neutrophils, 51 per cent; monocytes, 11 per cent, lymphocytes, 25 per cent; eosinophils, 4 per cent, basophils, 1 per cent. The Kahn test was negative, blood glucose was 94 mg. per cent, blood urea nitrogen was 9.5 mg. per cent; urine test was negative for albumin and sugar; urine test was also reported to be negative on December 1.

On January 29, 1943 a sternal marrow aspiration was performed. This yielded a marrow of low cellular count (18,000 in 1 cm., the average normal count being 100,000); the differential count revealed 8 per cent plasma cells; otherwise there was normal cell distribution: myeloblasts, 1.5 per cent, promyelocytes, 1.75 per cent; neutrophilic myelocytes, 28 per cent; eosinophilic myelocytes, 3.25 per cent; nonsegmented neutrophils, 16.5 per cent, segmented neutrophils, 20 per cent, eosinophils, 2 per cent, lymphocytes, 10 per cent; hematogones, 1.5 per cent; erythroblasts, 1.5 per cent; normoblasts, 11 per cent. Although the number of plasma cells was not excessive, their appearance seemed to be atypical because of numerous mitotic figures with double nuclei and also nucleoli, uneven staining, and pronounced vacuolization of the cytoplasm. They were reported as plasma myeloma cells, and the diagnosis of myeloma was advanced. Studies

of blood chemistry and urine were repeated but the report failed to substantiate this diagnosis.

On January 29, 1913, no Bence-Jones proteins were found in the urine there was no albumin, no sugar, in the blood were found albumin, 1.8 per cent, globulin, 0.8 per cent, calcium, 9.5 mg per cent, phosphorus, 4.5 mg per cent, phosphatase, 6.3 test of the serum content).

Schuller Christian disease had previously been suggested by some other observers, the blood cholesterol was determined on February 24, 1913, and was found to be 131 mg per cent.

In view of lack of confirmation of the diagnosis the sternal marrow aspiration was repeated on February 26, 1913. This time the total nucleated cell count was higher but still below the normal values, 11,000 in 1 cu mm. Plasma cells constituted 15.25 per cent and again appeared to be of the myeloma type. The increased number of plasma cells in this aspiration as compared to that of January 29 was interpreted as being due to a richer marrow obtained on this occasion, while that of the first aspiration contained a greater admixture of blood. This must have been the cause also of the "shift to the left" observed in the second aspiration owing to a larger proportion of pure marrow. The differential count was as follows: myeloblasts, 0.5 per cent, promyelocytes, 3.75 per cent, myelocytes, 33.5 per cent, nonsegmented neutrophils, 10 per cent, segmented neutrophils, 8 per cent, eosinophils, 4 per cent, monocytes, 1.5 per cent, lymphocytes, 7 per cent, plasma cells, 15.25 per cent.

March 5, 1913. The total nucleated cell count was found to be 28,000, with 10 per cent plasma cells. In light of the foregoing interpretation the number of plasma cells was explained as correlated to the total cell count, being dependent on the amount of aspirated blood.

On the basis of these bone marrow studies the diagnosis of myeloma was reaffirmed and repeated blood and urine studies as well as biopsy of the lesion were performed.

The results of urine analysis were the first to furnish confirmation for the diagnosis. On February 29 "albumin" was found in the urine in the amounts of 0.18 Gm total protein per 100 cm, and of 2.3 Gm total protein per twenty four hours. However, this "albumin" proved to consist for the most part of the Bence-Jones proteins. On March 5, 1913 the Bence-Jones test of the urine was reported faintly positive, but when I examined the urine on March 7, 1913, it contained large amounts

per cent, total globulin, 2.2 per cent, pseudoglobulin I, 1.1 per cent, pseudoglobulin II, 0.9 per cent, cuglobulin, 0.2 Gm per 100 cc. It was not before January 12, 1911, that a substantial rise in the blood was 9.1 per cent, and 2.6 per cent. I comprised 1.1 per cent, and cuglobulin 0.9 per cent. Other substances in the blood on that day were sugar, 93 mg per cent, urea nitrogen, 15.1 mg per cent, calcium, 11.9 mg per cent, phosphorus, 3.2 mg per cent, phosphatase, 6.5 B units.

Biopsy of a lesion in the skull, localized in the x-ray picture, was performed on March 8, 1913. Studying the smears made of the crushed biopsy material as well as of the centrifuged fluid in which these tissues were put, I found numerous plasma-like cells similar to those cells which I had observed in the bone marrow.

Myeloma it's general the course of his stay in the hospital. His blood count also showed improvement. On March 8, 1913, the hemoglobin was 70 per cent, the red blood count was 250,000, the white blood count was 13,000, non-segmented neutrophils, 1 per cent, segmented neutrophils, 80 per cent, lymphocytes, 7 per cent, monocytes, 7 per cent, eosinophils, 4 per cent, basophils, 1 per cent, Turck cell, 1 per cent. On May 10, 1913, the hemoglobin was 80 per cent, the red blood count was 4,800,000, the white blood count was 8,700. However, new lesions were discovered, on x-ray examination, in the left upper tibia and sixth right rib (x-ray report of February 20, 1913).

On August 12, 1913, the patient was discharged with his general condition much improved. He was readmitted on October 17, 1913, for pain over the left clavicle and a bony mass near the left sternoclavicular joint. He was again discharged on November 10, 1913, the pain having subsided and the swelling greatly diminished. On January 15, 1914, he sustained another pathologic fracture of the right arm and was readmitted to the hospital.

The patient was seen at frequent intervals during the time of his stay at home. His urine has almost always shown large amounts of Bence-Jones proteins, but the albumin almost disappeared. The blood count has been maintained at a normal level. There were no complaints except for the appearance of new lesions in the clavicle and arm mentioned above. Aspiration of the mass over the left sternoclavicular mass was attempted, but yielded only bloody material.

### Summary

A case of plasma-like cell multiple myeloma in a boy of 15 has been reported. At the time the diagnosis was made the patient gave a three-year history of bone pains and of pathologic fracture of the femur, so that at the onset of the present illness the patient was 12 years of age.

The diagnosis was made on the basis of bone marrow studies. Prior to that, the case had been diagnosed as osteosarcoma with metastases. At the time of the bone-marrow studies, no substantiating evidence for the diagnosis of multiple myeloma was found in either blood or urine examinations. The diagnosis was nevertheless advanced

Frequent urine examinations followed up in the subsequent months have showed intermittent appearance of Bence-Jones proteins in variable amounts, usually with albumin.

In the meantime blood studies repeated at fre-

quently was performed, showing albumin, 4.5

because atypical plasma-like cells were seen on repeated marrow aspirations. Subsequently, Bence-Jones protein appeared in the urine, at first only intermittently and in small amounts, but in the course of time appearing more often and in increasing amounts. Pathologic examination of a biopsy specimen of one of the skull lesions confirmed the diagnosis. Finally, the blood proteins, at first showing a low normal level with an especially low globulin content, started to rise, attaining 9.1 per cent protein as compared to 5.2 per cent at the time when the first bone marrow aspiration was performed. The high serum albumin and euglobulin fractions were significant (Gutman *et al.*).<sup>13</sup>

The case reported proves once more the importance of bone-marrow aspiration in the diagnosis of myeloma.

It proves also that youth should not rule out the possibility of this disease.

### CANCER SOCIETY ABSORBS FOUNDATION FOR CARE OF CANCER PATIENTS

The recently formed National Foundation for the Care of Advanced Cancer Patients has been absorbed into the thirty-one-year-old American Cancer Society. Under the arrangement the older group will devote part of the funds collected nationally to providing care for incurable cancer patients of moderate means, in addition to its present activities of supporting research and education in the prevention and cure of cancer. Its annual appeal is conducted in the spring. The amalgamation was announced by Dr. Clarence Cook Little, of the American Cancer Society, and Julius Jay Perlmutter, organizer and president of the Foundation, which was chartered last May. The organizations joined forces to avoid any confusion that might follow separate national campaigns for funds. The Foundation will temporarily maintain its offices at 1450 Broadway in New York City, but its activities and records will be transferred immediately to the Cancer Society's offices at 350 Madison Avenue.

Dr. Frank E. Adair, president of the American Cancer Society, who is also vice-president of the Foundation, said that the former group will stimulate establishment of hospitals and homes to care for hopeless cancer cases and contribute funds for their support. The organization had formerly emphasized educational campaigns in prevention and care of cancer in its early stages, contributing to the support of cancer research and detection clinics all over the country.

The organization announced a drive on May 27 for \$1,820,000 to provide 365,000 days of hospital care for incurable cancer patients and the ultimate aims of the organization were listed as the establishment of hospitals for cancer patients of this type where low-cost rooms and bath could be obtained.

The campaign was dropped at the request of the American Cancer Society, which said it was making arrangements to include the care of incurable cancer patients among its activities.

### MISS WORTHINGHAM JOINS NATIONAL FOUNDATION

Basil O'Connor, president of the National Foundation for Infantile Paralysis, has announced that Miss Catherine Worthingham, former president of the American Physiotherapy Association, has joined the National Foundation.

She will serve in the Medical Department as director of technical education, in which capacity she will assist in developing on a still wider scale the National Foundation's programs of undergraduate training and graduate education in physical therapy.

Miss Worthingham has been granted a leave of absence from Stanford University, where for the past seven years she has been director of physical therapy for women in the School of Health.

Her new assignment will embrace a thorough evaluation of the progress being made in the field of physical medicine through the application of modern physical and occupational therapy technics employed in the treatment of infantile paralysis patients. She will act in a liaison capacity between the National Foundation and the many treatment centers throughout the United States where training courses in this branch of medicine are being sponsored by the organization.

Miss Worthingham is a director of the American Physiotherapy Association; a member of the advisory committee, Office of Vocational Rehabilitation; and a member of the Clinical Research Subcommittee of the Baruch Committee on Physical Medicine.

She received her Bachelor's degree at Pomona College, California, and her Master's degree at the University of Southern California. Positions she has held include: instructor of physical education, Clifton (Ariz.) Union High School; physiotherapist, Orthopedic Hospital, Los Angeles; instructor in physical education at the John Muir Technical High School, Pasadena, and instructor and assistant professor at San Jose State College.

## Cardiology

POSTGRADUATE instruction for the Erie County Medical Society is to be held on November 28, 8:30 P.M., at Hotel Statler, Buffalo.

Dr. J. G. Fred Hiss, professor of clinical medicine at Syracuse University College of Medicine, will speak on "Common Errors in the Diagnosis of Heart

Disease with Special Reference to Rheumatic Heart Disease."

This instruction is presented by the Medical Society of the State of New York with the co-operation of the New York State Department of Health.

---

## MOVIES ON NEUROPSYCHIATRY MADE AVAILABLE THROUGH NEW YORK UNIVERSITY FILM LIBRARY

A series of motion picture films on neuropsychiatric disorders has been made available to medical and strictly scientific groups for educational purposes by a new department of medical films in the New York University Film Library.

The series of eleven films is the work of Dr. S. Philip Goodhart, chief of the neuropsychiatric division of Montefiore Hospital, New York, and professor of clinical neurology at Columbia University, and Maj. Benjamin Harris Balser, MC, consultant in neuropsychiatry, First Air Force, and associate in neurology at Columbia University.

The films have been used for a number of years in courses given to medical students at Columbia University and are now being made available for teaching purposes and professional discussion groups through the medical department of the New York University Film Library.

"The motion picture, with its exactness and brevity, is a medium admirably adapted to the teaching of neuropsychiatry," the announcement

states. "By this means, patients manifesting symptoms of various disorders can be assembled for classroom study. Moreover, the progress of a disease in one patient over a period of years can be studied via the terse medium of the film.

"Unusual disorders, infrequently encountered in ordinary practice, are made readily available for study. The audience can analyze characteristic movements by 'slow motion' and see the results of special studies covering many years. Different forms of motility, impossible to describe accurately by words alone, are vividly portrayed through the motion picture."

The announcement also points out that the films may be rerun so that study groups may review the great range of symptomatology presented.

The medical department of the film library is under the supervision of a committee of the New York University College of Medicine, and distribution of the films will be restricted to professional groups and organizations.

---

## NEW FOLDER DESCRIBES HEALTH DEPARTMENT SERVICES

An illustrated leaflet describing the organization and activities of the New York City Health Department has just been issued by the Department's Bureau of Health Education, it was revealed on September 27 by Health Commissioner Ernest L. Stebbins. Entitled "This Is Your Health Department," the new eight-page folder is designed to acquaint New Yorkers with the Health Department's widely varied activities. Single copies may be obtained without charge at District Health Centers throughout the city, or by writing directly to the New York City Department of Health, 125 Worth Street, New York 13, New York.

"All too many people in New York tend to think of their Health Department as an organization solely concerned with disease control and quarantine regulations," stated Dr. Stebbins. "They are not familiar with the many other Department services which range from producing life-saving vaccines and

serums and inspecting the city's food and milk supply to the operation of child-health stations and dental-hygiene services for city youngsters. However, unless the men, women, and children of the city are acquainted with these and the many other services of the Health Department they cannot be expected to derive the fullest benefit from them.

"The new leaflet is designed to introduce New Yorkers to these services by giving them a bird's-eye view of the entire Department, including the activities of each of its bureaus and divisions. I hope," concluded Commissioner Stebbins, "that all persons interested in what the Health Department is and what it can do for them will secure a copy of the folder at the earliest opportunity."

According to Savel Zimand, Director of the Bureau of Health Education, "This Is Your Health Department" is the tenth of a series of new pieces of literature produced by the Bureau during the past year.

IS  
SODA-BICARBONATE  
NECESSARY IN  
SALICYLATE THERAPY

To be effective, the treatment of acute rheumatic fever must maintain a high salicylate level in the blood.<sup>1</sup> When massive doses of sodium salicylate are given by mouth, an undesirable side effect—gastric distress—is frequently encountered. To relieve this effect, equal amounts of sodium bicarbonate are given. Unfortunately, a decided depression of the blood salicylate level results.<sup>2</sup>

Gastric distress and its required relief by sodium bicarbonate are avoided when Salysal is given, for Salysal is not soluble in the acid medium of the stomach. Furthermore, 100 parts of Salysal provide 12.4 equivalent parts of sodium salicylate.\* Thus, smaller doses accomplish the same effect.

## Forum on Allergy in Pittsburgh January 20-21

THE seventh annual Forum on Allergy will be held in the Hotel William Penn, Pittsburgh, on Saturday and Sunday, January 20-21, 1945.

Special lectures by outstanding authorities, study groups, pictures, demonstrations, symposiums, and panel discussions will comprise the program.

On Friday evening preceding the Forum, the American Association of Allergists for Mycological Investigation will hold its annual meeting, at which time the results of this group's cooperative research on allergy to fungi will be reviewed.

The Forum, which is an international postgraduate organization, was founded in 1938 at Cincinnati to provide a place in which to review the progress of clinical allergy, to provide in peacetime a forum for the younger members, and to offer intensive postgraduate instruction in allergy to physicians working in other fields. The founders were Dr. Tell Nelson, Chicago; Dr. Karl D. Figley, Toledo, Ohio; and Dr. Jonathan Forman, Columbus, Ohio. Annual meetings have been held each year since, in Toledo in 1939; in Chicago in 1940;

in Indianapolis in 1941; in Detroit in 1942; in Cleveland in 1943; and in St. Louis in 1944.

In 1940 the Forum's Gold Medal and annual oration were established as a means of recognizing outstanding contributions to clinical allergy. The first recipient was Dr. Béla Schick, New York City, who introduced the word "allergy"; the second was Dr. W. W. Duke, Kansas City; the third, Dr. Arthur F. Coca, New York City; the fourth, Dr. Robert A. Cooke, New York City. This year the Forum medal goes to Dr. Milton J. Rosenau, Chapel Hill, North Carolina.

This year the Marcelle Prize has been established through the courtesy of the Marcelle Cosmetics, Inc., and will be given to the author of the best paper on allergy to appear in the American medical literature during the year. The first prize will be \$350 and the second prize \$150. The awards will be based on the decision of a jury of distinguished allergists.

For further information, copies of the book, and registration, write Jonathan Forman, M.D., Director, 956 Bryden Road, Columbus 5, Ohio.

## National Committee for Mental Hygiene Meets in New York

THE thirty-fifth annual meeting of the National Committee for Mental Hygiene was held in New York City November 8-9. Topics of the sessions were "Mental Hygiene of Industry and Reconversion," "Rehabilitation and the Returning Veteran," "Race Relations," and "Services to the Mentally Ill Today." The luncheon session was devoted to the discussion of "Mental Hygiene Considerations in Peace Plans." Chairmen of the sessions were Dr. C. C. Burlingame, Psychiatrist-in-Chief, the Institute of Living, Hartford, Connecticut; Mrs. Anna Rosenberg, Regional Director, War Manpower Commission, New York City; Dr. V. T. Thayer, Educational Director, Ethical Culture Schools, New York City; Dr. James S. Plant, Chairman, Executive Committee, National Committee for Mental Hygiene; and Dr. Samuel W. Hamilton, Mental Hospital Advisor, Division of Mental Hygiene, United States Public Health Service, Washington, D.C.

The speakers and their topics were as follows: Col. H. Edmund Bullis, War Department, "The Hazards of Industrial Changeover"; Dr. Bruno Solby, U.S.P.H.S., "The Meaning of Mental Hy-

giene in Industry"; Dr. Matthew Brody, Brooklyn, "Dynamics of Mental Hygiene in Industry"; Dr. Sol W. Ginsburg, New York, "Community Responsibility for Neuropsychiatric Discharges"; Capt. Wilson R. G. Bender, "The Man as He Leaves the Service"; Mrs. Ethel Ginsburg, New York City, "Veteran Into Civilian—The Process of Readjustment"; Dr. Thomas A. C. Rennie and Luther E. Woodward, Ph.D., New York City, "Rehabilitation of the Psychiatric Casualty"; H. Scudder Mekeel, Ph.D., Madison, Wisconsin, "Cultural Aids to Constructive Race Relations"; Mr. Robert L. Cooper, Esopus, New York, "Frustrations of Being a Member of a Minority Group: What Does It Do to the Individual and to His Relationship with Other People?"; Harry C. Oppenheimer, New York City, "Nondiscriminatory Hospital Service"; Leonard Edelstein, Philadelphia, "Dangers to Our Care of Patients"; and Dr. Frank F. Tallman, Columbus, Ohio, "What the Mental Hygiene Program of a State Might Be." At the luncheon session Lyman Bryson, of the Columbia Broadcasting System, spoke on "The Effect of Peace Conditions on International Amity."

## City Takes Steps to Combat Rabies

IN AN effort to curb the outbreak of rabies, New York City patrolmen on October 18 were ordered by Police Commissioner Lewis J. Valentine to issue summonses to all dog owners who violate the provisions of the Sanitary Code by allowing their pets to run without a leash. Those found guilty will face a maximum fine of \$500 or one year in jail. This order was issued by Commissioner Valentine after a conference held recently with Health Commissioner Ernest L. Stebbins. Not only will summonses be served on the dog owners found violating the law, but police officers have been instructed by Commissioner Valentine to obtain the license

number or any other identification in case of dogs not accompanied by their owners. Police officers will then locate the owners and serve summonses to them.

"Despite repeated warnings," stated Police Commissioner Valentine and Health Commissioner Stebbins, "the people of New York do not seem to realize the grim seriousness of the present rabies outbreak. Urged over and over again to keep their dogs leashed when out of doors, they have persisted in allowing them to run at large on the streets and in the parks. As a result, the disease which . . . for

[Continued from page 2498]

a while . . . was limited to the borough of the Bronx has now spread to other parts of the city. The time for temporizing has passed. We must employ the strongest methods at our command to get this terrible disease under control before it begins taking a heavy toll of human as well as animal life.

"Since 1934 there has been a section of the Sanitary Code stating that 'No dog shall be permitted at any time to be on any street or in any public park or place in the City of New York, unless effectively restrained by a chain or leash not exceeding six feet in length.' (Section 17, N.Y.C. Sanitary Code.) If the people had obeyed this law and kept their pets on a leash, we would not today be faced with the danger of a city-wide outbreak of rabies.

"However, in view of the dire seriousness of the present situation, we propose to see that this law is obeyed. All members of the Police Department have therefore been directed to issue court summonses to dog owners who allow their dogs to run at large without a leash. Those found guilty of violating Section 17 of the Sanitary Code are subject to a maximum fine of \$500 or one year in jail. This meas-

ure is absolutely necessary to safeguard the health of the city."

Condemning the indifference of many dog owners, which they charged was "responsible for the current rabies outbreak," they stated that "One woman in New York City has already died from the bite of a rabid dog.

Unless the public cooperates more fully in the control of this disease, other victims may shortly follow."

Commissioners Valentine and Stebbins pointed out that the Police Department order in no way modifies the current ruling that all unleashed dogs must be picked up by the A.S.P.C.A. and destroyed unless arrangements are made within forty-eight hours to maintain them in approved quarters for a six months' isolation period.

Following the conference between Commissioner Valentine and Commissioner Stebbins, the problem was placed before Chief Magistrate Henry J. Curran, who is in full agreement with the need for the action taken by the Police Department.—*Release from the Police Department and the Department of Health, New York City*

### Seventh Session of School of Malariaology Held in October

FIFTY-FIVE Medical Department officers were selected to attend the seventh session of the Army School of Malariaology in the Panama Canal Zone starting October 13.

The officers who attended received a four-week course of instruction which included training in entomology, parasitology, the sanitary-engineering aspects of malaria control, the use of insecticides,

larvicides, and repellents, and the suppressive and clinical treatment of malaria.

The school, which is under the command of Col. Charles G. Souder, MC, was opened last February, and combines in a suitable location the various facilities used by the Army to train specialists in malaria control.—*Release from the Office of the Surgeon General, Oct. 16, 1944*

### New Army Bulletin on Gonorrhea

PENICILLIN is the drug of choice in the treatment of gonorrhea, according to a new War Department bulletin (TB Med 96). The use of sulfonamides, it says, will be limited to those cases not responding to adequate penicillin therapy and those instances in which penicillin is not available through normal supply channels. However, it is particu-

larly important, the bulletin warns, that patients with gonorrhea treated with penicillin be carefully followed with respect to the possible development of primary and secondary syphilis which may be retarded or masked by the penicillin therapy.—*Release from the Office of the Surgeon General, Oct. 16, 1944*

### Red Cross to Study Its Medical Work

BASIL O'CONNOR, chairman of the American Red Cross, has announced the appointment of a special medical and health committee composed of eleven men, prominent in their respective fields, to survey current Red Cross medical and health operations and to recommend plans for the postwar period.

In emphasizing that health and medical problems touched "virtually every aspect of Red Cross activities, whether in terms of disaster relief, nursing, accident prevention, nutrition, or blood donations," Mr. O'Connor said that he had asked the committee to survey "what we are doing currently, analyze the results achieved, and give me a blueprint of possible Red Cross activities in these fields in the postwar period."

Dr. Lewis Weed, of the Division of Medical Sciences, National Research Council, will serve as chairman of the committee, and Dr. Felix J. Underwood, of Jackson, Mississippi, president of the American Public Health Association, will be vice-

chairman. The secretary of the committee will be Dr. Henry R. Viets, lecturer on neurology at Harvard Medical School. Other members include Dr. George Baehr, director of clinical research at Mt. Sinai Hospital, New York City; Dr. Wilburt C. Davison, dean and professor of pediatrics, Duke University Medical School, Durham, North Carolina; Dr. Morris Fishbein, editor of the *Journal of the American Medical Association*, Chicago; Dr. Alan Gregg, director of the division of medical sciences, Rockefeller Foundation, New York City; Dr. Frank Lahey, Boston, national chairman of the directing board, Procurement and Assignment Service for Physicians, Dentists, Nurses, Veterinarians, and Sanitary Engineers; Dr. Roger I. Lee, Boston, president of the American Medical Association; Maj. Gen. Norman T. Kirk, Surgeon General of the Army; Vice-Admiral Ross T. McIntire, Surgeon General of the Navy; and Dr. Thomas Parran, Surgeon General of the U.S. Public Health Service.

## Hygeia Editor Tells of Goals for Physical Fitness Program

THE goals of the campaign for physical fitness, started September 1 by a Joint Committee on Physical Fitness, representing the American Medical Association and the National Committee on Physical Fitness, are outlined in the September issue of *Hygeia, The Health Magazine*, in an editorial "Keep Fit and Like It," by Morris Fishbein, M.D. This campaign, he declares, may prove to be one of the greatest possible significance to the health and happiness of the American people. Dr. Fishbein says:

"The great victories which are being won by American troops all over the world are not being won by men who are weaklings. In this war the American soldier has proved himself to be a competent fighter. He represents a selection of the best physical specimens that our nation has developed. To a group of men selected by the Selective Service and then reexamined by the physicians of the Army and Navy medical departments have been applied technics for physical and military training that the years have proved to be efficient.

"On the basis of available facts and figures, the American people are today probably the healthiest people in the world. Our sickness and death rates are among the lowest of all the great nations. Certainly our standards of living and the state of our nutrition are well up to the best that nations as a whole can demonstrate. However, there are still great areas of need. The 4,000,000 men rejected by Selective Service because they could not meet physical or mental standards are in need of what medicine and physical training have to offer. Many of the registrants were found to be pampered and soft and in need of conditioning. It would be folly for a nation as wealthy and as efficient as ours to fail to give to these people the most that medicine and physical training can give in order to make them effective.

"Modern medicine knows that not every person who is mentally or physically unfit can be benefited. Many defects are not preventable with the knowledge that medicine now has to offer. Numerous defects cannot be corrected. Perhaps 1,500,000 of the 4,000,000 referred to would be in this category. Nevertheless, that would leave 2,500,000 men who could be benefited by the application of proper medical treatment and modern physical conditioning. Many of these men could be made to meet the needs of the armed forces. Most of them could be made much more effective in the occupations which they fill in civilian life.

"The doctors of the United States have joined with the National Committee on Physical Fitness in the development of a Joint Committee which is going to emphasize physical fitness as a special job for the year beginning September 1, 1944. The knowledge that medicine has gained about life and health and the program that has been established by experts in the field of physical education and recreation will be combined to overcome as many

as possible of the preventable and correctable defects that were responsible for the rejection of two thirds of the men who were summoned to the armed forces. The physicians have the responsibility for inventory before and after the establishment of the physical fitness program to determine the nature of the difficulties to be overcome and then to determine how well the results have been accomplished.

"Even ordinary physical fitness requires development. Physical fitness is a bodily state in which the tissues have power and efficiency. The basic material of the American body is sound; it needs training.

"The purpose of the campaign is not the development of big muscles. Physical fitness implies that the heart, lungs, teeth, eyes, and other organs are physically sound and capable of working efficiently. Physical fitness implies specific fitness or skill in certain performances. Physical fitness is needed not only by the high school and college students and by the armed forces but by every man and woman in this country. Especially is physical fitness needed in industry, where the fitness of every worker must be geared to his job. The Council on Industrial Health of the American Medical Association, working with representatives of management and labor, is concerning itself particularly with determining the physical condition of workers and maintaining continuous records of the workers' health and fitness.

"Physical fitness includes the practice of good personal hygiene and the application of established knowledge to improving the health and fitness of the human body. It includes enough sleep, the right kind of ventilation, and continuous emphasis on cleanliness. It demands proper nutrition, good posture, controlled exercise, and rest periods. It embraces mental hygiene and a program of recreation.

"In Washington on July 27 and 28 a conference was held under the auspices of the Joint Committee of the American Medical Association and the National Committee on Physical Fitness in which more than one hundred leaders in all the fields concerned took part. Out of that conference came a program. The Joint Committee on Physical Fitness has adopted these goals:

1. Help each American learn physical fitness needs.
2. Protect against preventable defects.
3. Attend to correctable defects.
4. Know how to live healthfully.
5. Act to acquire physical fitness.
6. Set American standards of physical fitness at high levels.
7. Provide adequate means for physical development.

"The year of special emphasis on physical fitness initiated by this conference may well prove to be one of the greatest possible significance for the health and happiness of the American people."—*A.M.A. News*

## Old Friend—New Name

EFFECTIVE May, 1944, the historic Henry Street Visiting Nurse Service of New York City became officially the "Visiting Nurse Service of New York." The change of name in no way affects the far-reaching public service maintained by this institution since its founding fifty years ago by the late

Lillian D. Wald. Headquarters still are at 262 Madison Avenue; the telephone still: "Caledonia 5-0900." And, as always, it continues to supply part-time skilled nursing care to the sick in their own homes, and lends its aid to safeguarding the

[Continued on page 2504]

**TABLETS FOR *Oral* USE—  
AMPULS FOR *Injection***

There has long been a real need for a potent, mercurial diuretic compound which would be effective by mouth. Such a preparation serves not only as an adjunct to parenteral therapy but is very useful when injections can not be given.

After the oral administration of Salyrgan-Theophylline tablets a satisfactory diuretic response is obtained in a high percentage of cases. However, the results after intravenous or intramuscular injection of Salyrgan-Theophylline solution are more consistent.

Salyrgan-Theophylline is supplied in two forms:

**TABLETS** (enteric coated) in bottles of 25, 100 and 500.  
Each tablet contains 0.08 Gm. Salyrgan and 0.04 Gm. theophylline.

**SOLUTION** in ampuls of 1 cc., boxes of 5, 25 and 100;  
ampuls of 2 cc., boxes of 10, 25 and 100.

[Continued from page 2502]

health of the community, regardless of race, color, religion, or ability to pay.

Coincident with the change of name, the Visiting Nurse Service has been incorporated as a separate organization. The Henry Street Settlement continues as a neighborhood house on the lower East Side, Manhattan, and the Visiting Nurse Service will carry out its program to give part-time skilled nursing care in homes throughout the boroughs of Manhattan, Bronx, and Queens, as heretofore.

Of major interest in the reorganization of the Visiting Nurse Service is the inclusion of physicians as regular members on the board of directors, for the first time. Dr. George W. Kosmak, who has been chairman of the Medical Advisory Committee of the Service for many years, and Dr. Haven Emerson and Dr. Harry Aranow, both long-time members of the advisory body, are continuing their association as directors in the new organization.

The Medical Advisory Committee has in the past been an auxiliary committee without executive powers, but now is made one of the subcommittees of the Board, with its chairman a member ex-officio of the Executive Committee. Board members are elected for a term of office not to exceed three years, and provision is made in the bylaws for a rotation of committee chairman.

Also for the first time, nurses have been named members of the board. Those just elected are: Miss Isabel Stewart, professor of nursing education at Teachers College, Columbia University, and Miss Marion W. Sheahan, director of the Division of Public Health Nursing, New York State Department of Health, and president of the National Organization for Public Health Nursing.

It is felt that the inclusion of medical and nursing personnel on the board greatly strengthens the program of the Visiting Nurse Service.

Under the recent reorganization, James L. Harrison becomes president of the Visiting Nurse Service

and R. Gordon Wasson, treasurer, George W. Alger remains as the chairman of the board.

The Nursing Service is available to all patients whose physicians are prepared to give the nurses orders for treatments, medication, etc., irrespective of the patients' ability to pay for the nurses' visits. Physicians can call for the services of a visiting nurse when their patients first return home from the hospital, or whenever they have patients sick at home, or whenever there are any other health problems in the home. Although all first calls coming to the Service are answered by a home visit, *no patient can be cared for who is not under medical supervision*. Patients not under medical care are urged to obtain it. Service given on such first visits is limited to basic necessities, as approved by the Medical Advisory Committee of the Service.

Care is given *free or below cost*, as always, to those unable to pay. Public contributions make this possible. Care is given *at cost* to those who can pay. The cost is \$1.50 for a visit lasting not longer than three-quarters of an hour (50 cents for each additional quarter hour). Experience shows that less than an hour is sufficient for the average call.

Fee adjustments are made individually by the nurses at the time of their visits. The organization invites recommendations from physicians as to the amount of adjustment indicated.

The nurses are on duty from 8:30 A.M. to 5:00 P.M. daily, except Sundays and holidays, when only emergency calls can be answered. They will stay with the patients as long as necessary but no longer. Other patients are waiting for them.

The Visiting Nurse Service is willing, on request, to send a member of the administrative staff to explain to any physician in detail about its management and over-all program. To make arrangements for such a visit, or to refer patients for nursing care, physicians are invited to telephone the Visiting Nurse Service of New York, Caledonia 5-0900. The director is Marian G. Randall, R.N.

## County News

### Albany County

The speaker at the county society meeting on October 25 was Dr. Samuel M. Peck, Senior Surgeon (R) of the U.S. Public Health Service. The title of his address was "Problems in Industrial Dermatoses." Discussion of the paper was opened by Dr. Rudolph Ruedemann, Jr., of Albany.

In a recent address before the Exchange Club of Utica, Dr. John B. Congdon, of Albany, appealed to the members of that organization to work against the proposed program of socialized medicine.

Dr. Congdon, who is regional vice-president of the Exchange Clubs, said that he spoke on behalf of the "white-collar man in the middle class who under socialized medicine would not be able to select his own physician but would have to take one from a Federal panel." \*

### Allegany County

A regular meeting of the county society was held in Belmont on October 12.

The Allegany County Professional Registered Nurses' Association joined the society at dinner, after which the two groups held separate business meetings. Dr. Wallace Hamby, of Buffalo, was the speaker at the county society meeting.\*

### Bronx County

A regular meeting of the county society was held at Burnside Manor on October 18 at 8:30 P.M.

Following an executive session, Dr. Moses H. Krakow, newly elected president of the county society, gave his inaugural address.

The other speaker on the evening's program was Dr. Herbert H. Bauckus, President of the Medical Society of the State of New York, who spoke on "Medical Expense Insurance." Discussion was led by Drs. Milton J. Goodfriend and John L. O'Brien.

Montefiore Hospital for Chronic Diseases, the Bronx, has opened a clinic for the diagnosis and treatment of convulsive disorders and migraine under the auspices of the Division of Neuropsychiatry, with Dr. H. Houston Merritt as chief of division.

The clinic will be held on Mondays at 9:00 A.M. in the Hospital's Follow-Up Clinic. In addition to patients who require the clinic services because of lack of funds, patients recommended by the family physician for diagnosis and special therapy will be accepted for treatment both in the clinic and in the wards.

the gold medal whiskey

*since 1872*

Distilled in peace time and Bottled in Bond  
under the supervision of the U. S. Government.

(Continued from page 2504)

**Chautauqua County**

Dr. George W. Cottis, of Jamestown, past president of the Medical Society of the State of New York, was elected chairman of the Board of Visitors of the State Institute for the Study of Malignant Diseases. The organization meeting was held in Buffalo on October 10.

**Columbia County**

At the annual meeting of the county society held in Hudson on October 3, Dr. Everett Jacobs read a paper entitled "The Clinical and X-Ray Diagnosis of Ruptured Duodenal Ulcers."

Dr. Frank Maxon, of Chatham, spoke on behalf of the proposed new Columbia Memorial Hospital.\*

**Dutchess County**

On October 1 the Associated Hospital Service of New York made its surgical service plan operative in Dutchess County, under a merger with the Medical Expense Fund of New York, Inc.

Dr. Chester O. Davison was the local director of the Medical Expense Fund, which was one of several medical insurance plans which were recently merged into the United Medical Service, Inc.\*

. . .

Dr. Harry LaBurt, president of the county society, has announced the appointment of a committee to investigate the possibility of providing communicable-disease hospital facilities in the county. Physicians who will serve in this capacity are: Dr. Scott Lord Smith, representing Vassar Brothers Hospital; Dr. James E. McCambridge, of St. Francis Hospital; Dr. L. Edward Cotter, of Red Hook, representing the Northern Dutchess Health Center; and Dr. Edgar F. Powell, of Fishkill, representing Highland Hospital of Beacon.

The county Board of Supervisors and the Poughkeepsie Board of Aldermen have been invited to name four members of this study committee.\*

**Fulton County**

Dr. Percy Pelouze, authority on venereal diseases, was guest speaker at a meeting of the county society held in Gloversville on September 28. His topic was "Gonorrhea."

Dr. Morris Kennedy, of Gloversville, president of the county society, conducted the business session and introduced the speaker.

Among the other guests at the meeting were Dr. James H. Lade, Director of the Division of Syphilis Control of the State Department of Health; Dr. Robert S. Westphal, assistant director in the same department; and Dr. James J. Quinlivan, of Amsterdam, district health officer.

Preceding the program dinner was served to thirty members and guests.\*

**Genesee County**

Dr. Carl C. Koester, of Batavia, was re-elected to the Board of Trustees of Kiwanis International at that organization's wartime convention held recently in Chicago.

Dr. Koester is a member of the staff of Genesee Memorial Hospital, chief of the nose and throat department at St. Jerome's Hospital, consultant to the United States Veterans Facility, attending surgeon at Buffalo Eye and Ear Infirmary, and con-

sultant otolaryngologist for the Batavia school system.

He is in addition a member of the Selective Service Medical Advisory Board in Batavia, a past vice-chairman of the Medical Defense Committee, and a past president of the county medical society.\*

**Greater New York**

Three New York physicians are borough chairmen of Physicians' Committees in the campaign of the Visiting Nurse service of New York which opened October 26. They are: Dr. George W. Kosmak, Manhattan; Dr. Harry Aranow, the Bronx; and Dr. Miller A. Sanders, Queens.

. . .

Edward Corsi, New York State Industrial Commissioner, has made the following appointments to the Medical Practice Committee as authorized by Chapter 459 of the Laws of the State of New York: Dr. Francis Michael Conway, New York County, *chairman*; Dr. E. Welles Kellogg, Queens; and Dr. Joseph Raphael, Kings County.

**Greene County**

Dr. William Vernon Wax, of Catskill, has been elected to the International College of Surgeons. He is also a member of the Association of Military Surgeons of the United States.\*

**Herkimer County**

Dr. Frank L. Meleney, of New York City, was the guest speaker at the meeting of the county society held at the Palmer House in Herkimer on October 10. His subject was penicillin therapy.

During the annual business meeting officers for the coming year were nominated, the election to take place at the December 12 meeting.\*

**Kings County**

A stated meeting of the county society and the Academy of Medicine of Brooklyn was held on the evening of October 17, with a symposium on modern medical problems as the feature of the scientific program. Dr. Jean Curran, president and dean of the Long Island College of Medicine, gave an address entitled "Medical Education—Its Relationship to Problems of Modern Practice." The other speaker was Dr. Morris Hinenburg, executive director of Brooklyn Jewish Hospital, whose topic was "Health Insurance and the Hospital."

. . .

The medical profession was invited to attend a special meeting on "Rehabilitation and Tuberculosis" of the Kings County Medical Society at 4:00 P.M. on October 31.

The program was presented by four speakers. The first was Mr. Edward T. Fagan, chairman of the Rehabilitation Committee of the Brooklyn Tuberculosis and Health Association, who presided. The medical aspects of the topic were discussed by Dr. Thomas N. Sheen, clinical consultant of Triboro Hospital. The social and economic aspects were presented by Miss Margarette B. Helmle, rehabilitation secretary of the Brooklyn Tuberculosis and Health Association. Mr. Edward Hochhauser, executive director of the Committee for the Care of the Jewish Tuberculous, had as his phase of the subject the industrial aspects. A general discussion followed the main addresses.

# Still Making Good ON PRE-WAR PROMISES

It's calls like this, as frequent today as in the pre-war years, that best serve to explain why G-E x-ray and electromedical equipment continues to efficiently meet the abnormal service demands of wartime civilian practice.

Verily, G-E customers appreciate today, as never before, the value and importance of G-E's *Periodic Inspection and Adjustment Service*. For in face of the unprecedented load imposed on the medical home front, and the difficulty of obtaining new and additional equipment that would facilitate the handling of this increased amount of work, there was but one alternative: to get the most possible service out of existing equipment, for the duration.

Many an investment in G-E equipment has been based on the assurance that this organization would always maintain a nationwide field organization whereby expert technical and maintenance service is conveniently available at all times. And G-E's *P. I. and A. Service* has been consistently making good that promise—despite many wartime handicaps—in G-E equipped hospitals, clinics, and physician's offices throughout the United States and Canada.

Similarly we are determined to justify your future investments in G-E products, by supplementing their well-known high quality and efficiency with a competent field service.

Write for the headquarters address of our local representative, who stands ready to help you plan for your present or future needs.

X-RAY CORPORATION**

2012 JACKSON BLVD.

CHICAGO (12), ILL., U. S. A.

[Continued from page 2506]

The last two Friday Afternoon Lectures for November will be given in MacNaughton Auditorium at 4:00 p.m. on November 17 and November 24. The first will be "Diagnosis and Treatment of Amebic Infection," by Dr. Howard B. Shookhoff, epidemiologist in Tropical Diseases, New York City Department of Health. The second lecture, entitled "The Pneumonias of Early Infancy," will be delivered by Dr. Benjamin Kramer, chief pediatrician of the Jewish Hospital of Brooklyn.

There will be a meeting of the Pediatric Section of the county society on Monday evening, November 27. Dr. Matthew Walzer will speak on "Food Allergy in Infancy and Childhood."

#### Madison County

The one-hundred and thirty-eighth annual meeting of the county society was held at the Hotel Oneida in Oneida on October 26. Dinner was served to members and guests at 6:30 p.m. and business and scientific programs followed, at 8:00 p.m. "The Medical Indemnity Insurance Program" was the first address. The speaker was Dr. Leo F. Gibson, of Syracuse, chairman of the Medical Indemnity Insurance Committee of the Onondaga County Medical Society. The first scientific paper of the evening was "Traumatic Surgery with Emphasis on the Treatment of Wounds and Shock," by Dr. Emmett A. Dooley, assistant clinical professor of surgery, New York Post-Graduate Medical School, Columbia University. The second paper was one by Dr. Ivan Hekimian, entitled "The Therapy of Thyroid Disorders, Including Thiouracil." Dr. Hekimian is assistant professor of medicine at the University of Buffalo School of Medicine.

This program was arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York, in co-operation with the State Health Department.

#### Monroe County

Dr. John L. Norris, of Rochester, addressed the Western Division of the Practical Nurses of New York at a meeting in Monroe County Hospital on October 3. His topic was "Communicable Diseases."

#### Nassau County

A regular monthly meeting of the county society was held on October 31 in Mercy Hospital Auditorium in Rockville Centre.

The speaker was Dr. Frank L. Meleney, associate professor of clinical surgery at the College of Physicians and Surgeons, Columbia University. His subject was "Penicillin."

This lecture was one of a number of programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York.

Dr. Louis H. Bauer, of Hempstead, a past president of the county society, is now one of the nine members of the board of trustees of the American Medical Association.

#### New York County

H. R. Ickelheimer, New York banker who died in

1940, bequeathed \$25,000 to Cornell University for cancer research.

Dr. René J. Dubos, of the Rockefeller Institute for Medical Research, New York City, spoke on tyrothricin and gramicidin at the *Herald Tribune* Forum in New York City on October 17, 1944.

The Clinical Pathological Conferences of the Mount Sinai Hospital were resumed on October 18 at 3:30 p.m. in Blumenthal Auditorium. They will be continued weekly at that time. Members of the medical profession are invited to attend.

Dr. Bret Ratner was one of the guest speakers at the refresher course given by the Medical College of the State of South Carolina on November 1 and 2 in Charleston, South Carolina. He spoke on "The Allergic Child" and conducted a round-table discussion on "Eczema in Children."

#### Oneida County

Dr. F. K. Gifford has opened an office in Rome, where he will practice as a urologist.

Dr. Gifford is also serving his second term as county coroner.\*

The October meeting of the county society was held at Rhoads Hospital at 8:00 p.m. on October 10. Capt. Daniel Feldman spoke on "War Injuries of the Extremities"; there was also clinical demonstration.

The Utica Academy of Medicine met at the Hotel Utica on October 19 for dinner at 7:00 p.m., followed by a scientific program at 8:00 p.m. The speaker was Dr. Francis R. Irving, of Syracuse, who discussed "Caudal Anesthesia in Obstetrics" and illustrated the lecture with lantern slides and motion pictures. The discussion was opened by Drs. Robert Sloan and B. Victor Di Iorio.

Dr. T. Wood Clarke, of Utica, conducted a half-day class on allergy of the central nervous system at the five-day intensive graduate course in allergy which was given by the American College of Allergists in St. Louis, November 4-8.

#### Onondaga County

"The faster medicine changes, the more certain it is that men and women in medicine must train themselves differently from their predecessors," Dr. C. Sidney Burwell, Dean of the Harvard Medical School, told forty-six Syracuse University College of Medicine graduates.

Dr. Burwell addressed the graduates at commencement exercises on September 24 in the medical school auditorium, at which he received an honorary doctor of science degree.

Three women were the only civilians in the class. Thirteen naval students among the graduates were commissioned lieutenants, junior grade, in the U. S. Naval Reserve by Lt. (j.g.) James H. Roberts, and

# Announcing

## Desenex

A *Specific* for the  
**Superficial Fungous Infection**  
**ATHLETE'S FOOT**

Desenex, a new development of the widespread war research, represents the successful therapeutic application of fatty acids for the treatment of this prevalent and stubborn condition.

The active ingredient of Desenex is undecylenic acid. This unsaturated fatty acid is as harmless to the skin as stearic acid, which is widely used in cosmetics. Surprisingly, however, this generally inert substance is as *specific and potent in its action on fungi* as some widely used chemotherapeutic agents are on other organisms.

Desenex may be used with confidence. Clinical cure of the troublesome fungous infection—athlete's foot—is generally achieved within a relatively short time by daily application of Desenex.

the thirty army men were commissioned first lieutenants in the army medical reserve by Lt. William D. Randall, company commander.\*

#### Ontario County

"John Barleycorn" was the title of a paper read by Dr. Margaret T. Ross at the October meeting of the Canandaigua Medical Society on October 6. Members of the society were the guests of Dr. A. W. Armstrong at his home.

Dr. Malcolm Blakeslee, of Shortsville, was host to the members for the meeting on November 3, at which Dr. F. C. McClellan, acting president, was reader.\*

#### Orange County

Dr. Daniel Burman, a veteran of World War II and an eye, ear, nose, and throat specialist, has opened an office in Newburgh.\*

#### Queens County

The Rockaway Medical Society held a meeting on October 19 at the Lawrence Village Parkhouse, with Dr. Benjamin Jablons, chief of vascular diseases at Beth David Hospital, New York City, as the speaker. The discussion was illustrated by motion pictures and lantern slides.

Dr. Herman Gliboff, president of the society, presided.

. . .

Industrial medicine was the subject of the scientific program at the county society's stated meeting on October 31. The three addresses of the evening were: "The Evaluation of the Health Status of the Worker," by Dr. William A. Sawyer, medical director of the Eastman Kodak Company, Rochester, New York; "The Integration of Industrial Hygiene in Medical Practice," by Dr. J. G. Townsend, medical director of the Industrial Hygiene Division of the U.S. Public Health Service; and "Industrial Medicine and the General Practitioner," by Dr. C. F. Yeager, chairman of the committee on industrial health of the Connecticut State Medical Society.

The scientific session was preceded by a dinner at the Forest Hills Inn.

#### Rensselaer County

Dr. J. M. Purcell, of Troy, an alumnus of the New York Medical College, class of 1894, was presented with a gold diploma at the fiftieth anniversary of the class on September 28.

#### Richmond County

The United Medical Service, Inc., has been endorsed by the county medical society, Dr. D. V. Catalano has announced.

#### Saratoga County

On September 15 the Metropolitan Life Insurance Sanatorium at Mount McGregor honored Dr. William H. Ordway, physician-in-charge, for his twenty-five years of service to the institution.

Dr. Ordway has engaged in numerous medical activities in his community. He is a past-president of the county medical society and during the present war has served as chief of the Emergency Medical Saratoga Civilian Defense Organization.

#### Seneca County

The regular annual meeting of the county so-

cietiy was held at Willard State Hospital on October 12. The business meeting at 10:30 A.M. was followed by luncheon at 12:30 P.M. and a scientific session at 2:00 P.M. The speakers were Dr. Leon H. Griggs, associate professor of dermatology at Syracuse University College of Medicine, who discussed "Some Common Forms of Skin Diseases," illustrated by colored lantern slides, and Dr. Angelo Raffaele, of the Willard State Hospital staff, who gave a lecture entitled "Electroshock Therapy in Dementia Praecox." About thirty members and guests were present at the meeting.

The following officers were elected at the meeting, to take office in January 1, 1945: president, Dr. Bruno Riemer, of Romulus; vice-president, Dr. Stanley B. Folts, of Lodi; censors, Dr. R. F. Gibbs, of Seneca Falls, Dr. E. P. McWayne, of Fayette, and Dr. Roy E. Wallace, of Seneca Falls; delegate to the State Society, Dr. W. M. Pamphilon, of Willard; alternate, Dr. Bruno Riemer; delegate to the seventh district branch, Dr. F. W. Lester, of Seneca Falls; and alternate, Dr. A. F. Baldwin, of Waterloo.

#### Sullivan County

At the annual meeting of the county society held in Liberty on October 11 the following officers were elected for the ensuing year: president, Dr. Ralph S. Breakey, of Monticello; vice-president, Mr. Nathan Nemerson, of Monticello; secretary-treasurer, Dr. Deming S. Payne, of Liberty; censors—Drs. Morris A. Cohn, of Monticello, Cornelius Duggan, of Bethel, Luther F. Grant, of Liberty, Jacob Kornblum, of Monticello, and George R. Mills, of Callicoon; compensation committee—Drs. Harry Golembe and L. F. Grant; alternates to compensation committee—Drs. Mills and Nemerson; delegate to the State Society, Dr. Benjamin Abramowitz, of Monticello; alternate delegate, Dr. Harry Golembe.

#### Tompkins County

A regular meeting of the county society was held at Herman M. Biggs Memorial Hospital in Ithaca on October 17. The program was a special one on cancer, sponsored by the Medical Society of the State of New York and the Division of Cancer Control of the New York State Department of Health.

The speakers at the afternoon session were Dr. John H. Garlock, attending surgeon, Mount Sinai Hospital, New York City, whose subject was "Carcinoma of the Colon," and Dr. John J. Morton, professor of surgery at the University of Rochester School of Medicine and Dentistry, who read a paper on "Bone Tumors."

Dr. Andrew H. Dowdy and Dr. Frank E. Adair were the speakers at the evening session. Dr. Dowdy, who is associate professor of radiology at the University of Rochester School of Medicine and Dentistry, gave an address entitled "Epithelioma of the Skin." "Carcinoma of the Breast" was the topic of Dr. Adair, who is executive officer at Memorial Hospital in New York City and president of the American Cancer Society.

Dinner was served at the Hospital between the afternoon and evening programs. Eighty-five persons attended the meeting.

#### Washington County

At the meeting of the county society held on October 10 the following officers were elected and appointed: president, Dr. Z. V. D. Orton, Salem; vice-president, Dr. L. A. White, Whitehall; secre-

[Continued on page 2512]

# FOR *Convenience* AND FLEXIBILITY OF DOSAGE

Bethiamin presents crystalline thiamine hydrochloride in three forms and in a range of dosages adequate for every need. • For oral administration palatable Bethiamin Elixir provides 6 mg. of thiamine hydrochloride per ounce, and Bethiamin Capsules

are available in dosages from 1 mg. to 15 mg. • For parenteral administration Bethiamin ampuls are available up to 100 mg. per cc. Thus Bethiamin places at the physician's hands dependable vitamin B<sub>1</sub> medication in the most convenient forms.

## BETHIAMIN

For oral administration, Bethiamin is available in capsules containing 1 mg., 3 1/3 mg., 10 mg., and 15 mg.; for parenteral administration, in 1 cc. ampuls containing 1 mg., 10 mg., 50 mg., 100 mg. and in 10, 30 or 60 cc. rubber-capped vials. In liquid form Bethiamin Elixir contains 6 mg. of thiamine hydrochloride per fluidounce.

Bennett, Granville, *chairman*: war participation committee—Drs. E. V. Farrell, Whitehall, R. E. Borrowman, Fort Edward, and Dr. D. F. MacArthur, Greenwich.

### Westchester County

Maj. Nicholas R. Locascio, former Yonkers and New York City physician who is prominent in the field of psychiatry, has been appointed Post Surgeon and Commanding Officer of the Army Station Hospital at Pine Camp, New York, Col. L. R. Clement, post commander, has announced.

He succeeds Col. Dunlap P. Penhallow, who has reverted to inactive status with the Army Medical Corps. Colonel Penhallow, post surgeon and Pine Camp Station Hospital commanding officer for more than two years, received retirement orders about two months ago but these were subsequently revoked and he continued to perform his duties. Recently he was again reverted to inactive status and has taken up his residence with his family in Philadelphia, New York.

Active in the Reserve Officers Corps from 1931 until he reported for active duty on June 2, 1941 at Ft. Hancock, New Jersey, Major Locascio has served with the Army Medical Corps in various capacities. He entered the service with the rank of captain, which he received in 1935, and on February 1, 1942, was promoted to major. During his period of service at Ft. Hancock, from June 2, 1941 to October, 1943, Major Locascio was post psychiatrist, chief of medical service, plans and training officer for the Station Hospital, and interval post surgeon. He played a prominent part in improvements in hospital facilities at Ft. Hancock and one of the major tasks assigned him while there was the training of a large number of Army nurses.

On October 9, 1943, Major Locascio was ap-

pointed post surgeon and chief psychiatrist of Eastern Branch, U.S. Disciplinary Barracks at Green Haven, New York. He remained in that capacity until March 22, 1944, when he was transferred to Pine Camp as chief of medical service and post psychiatrist of the Station Hospital.

Graduated from Fordham Preparatory School in 1923, the major received his A.B. degree from Fordham College in 1927 and his M.D. degree from Georgetown University Medical School in 1931. During the early part of his training at Georgetown, Major Locascio had as one of his instructors Colonel Penhallow, whom he is now succeeding at Pine Camp. He was granted his license to practice medicine in New York and Maryland in 1931 and he did postgraduate work in neuropsychiatry at Harvard Medical School and the Army Medical School, Walter Reed General Hospital, Washington, D.C.

From 1933 to 1941, Major Locascio was associated with the neurologic and psychiatric departments of the following hospitals: Morrisania City Hospital, Columbus Hospital, Mother Cabrini Memorial Hospital, City Hospital, and Welfare Island Dispensary all in New York City, and St. Joseph's Hospital in Yonkers. At the latter institution, he was a member of the Board of Directors. He also is a qualified examiner for the Department of Mental Hygiene of the State of New York.

Major Locascio is a member of the American Medical Association, Medical Society of the State of New York, Bronx County Medical Society, Yonkers Academy of Medicine, Bronx Medical Fraternity, American Psychiatric Association, and the Association of Military Surgeons.

### Wyoming County

The county society held its fourth quarterly meeting for the year on October 11, at which time the following officers were elected: president, Dr. A. Kosseff, Attica; vice-president, Dr. M. M. Graves, Warsaw; secretary, Dr. G. W. Mairn, Warsaw; delegate to the State Society, Dr. H. S. Martin, Warsaw; alternate delegate, Dr. G. S. Baker, Castile; censors—Drs. M. T. Greene, Castile, L. H. Humphrey, Silver Springs, and G. A. McQuilkin, Varysburg.

## SULFANILAMIDE IN SOLUTION •SURBYL

*Pioneered by  
STRASENBURGH  
Research*

● Surbyl is a balanced combination of Sulfanilamide, Urea and Benzyl Alcohol in a Propylene Glycol base.

Surbyl has been found valuable in the treatment of otitis media, paronychia, varicose ulcers, infections of the hand or foot and as a dressing for wounds and abscesses.

Surbyl Solution is free from excess alkalinity. The pH is between 7.5 and 8.0 which is a desirable range for topical administration.

Available in pint and gallon quantities. Write for professional folder S-12.

PHARMACEUTICAL CHEMISTS SINCE 1886

ROCHESTER, NEW YORK

# ETHER-IN-OIL

*Brewer*

AN ADJUVANT  
IN THE TREATMENT OF  
BRONCHIAL ASTHMA

Definite results in recently treated acute bronchial asthma cases, have proven the beneficial properties of ETHER-IN-OIL used in conjunction with other standard medications.

Six patients, having had an attack of acute asthma from two to five days, were thus treated (*Dr. Maietta, N. E. J. Med., Vol. 227, p. 985*). All of them responded fairly well, but not satisfactorily to injections of epinephrine. Four of them received one intramuscular injection of ETHER-IN-OIL, the remaining two received 2 each. Within two hours, the asthmatic symptoms were rapidly controlled. The patients became quieter, were able to breathe more easily and expectorate more freely. Thereafter, the usual palliative medications effectively controlled the symptoms.

ETHER-IN-OIL (Brewer) is recommended in addition to (or in conjunction with) Brewer's LUASMIN capsules and enteric-coated tablets—oral medication representing timed therapy in the symptomatic control of Bronchial Asthma.

# Hospital News

General Hospital's "pest" house, in Jamestown, which for several decades housed all manner of contagious cases, is to be torn down.

The Health and Hospital Board has advertised for bids to demolish the one-story frame structure and for salvaging of the electrical, heating, and plumbing materials it houses.\*

The three-week drive for funds to pay off the \$33,000 obligation of the Margaretville Hospital officially closed on August 25, with a total of \$17,260.

The reception center at Camp Upton, which has been an induction or training center for hundreds of thousands of men in two wars, will serve in the future as a hospital for convalescent soldiers, it has been announced by the public relations office.

Within a short time the Army's newest hospital, to be known as Second Service Command Hospital Unit 1234, is expected to be handling 3,000 patients. The center is capable of being developed for 5,000 patients.

The new hospital unit will be under the supervision of Col. Edward A. Coats, Jr.\*

An army hospital, the first of its kind in Chungking, has been opened at Kiangpei across the Yangtze River. General Ho Ying-chin, in his opening address, said that the hospital would meet a long-felt need to offer adequate medical care to officers and men. "Wartime limitations have considerably narrowed the scope of army hospital facilities," said General Ho. "The establishment of a well-equipped and well-staffed army hospital in a well-chosen site can be a good example to other parts of the country."\*

A study of practical nurse placement registries in the State preliminary to setting up a model registry in New York City was approved by the Committee for the Recruitment and Education of Practical Nurses at its initial fall meeting on September 19. The committee approved a budget appropriation of \$5,000 to finance the research, which will take a year to complete, and will cover salaries, hours, conditions of work, and fees.

Miss Hilda Torrop, executive secretary of the committee, said that the study would help to relieve a situation that at present is "chaotic," with few nurses available, and with little sound counselling being given by registries. On the basis of material gathered, a placement office will be opened here, which, she said, would be the "best of its kind" and manned by a well-prepared staff.

The war has given the public a rapid education, she added, in what services a practical nurse can render, with the result that 5,000 additional trained women are needed now, and will continue to be needed in postwar rehabilitation and public health work.

To meet the demands, the committee will intensify its campaign by doubling the number of refresher

courses given and by developing new fields for recruitment, especially within hospitals and schools. Fall enrollment in State-approved schools was reported to be 100 per cent higher than that of last year, with students averaging 25 years of age.

For its expanding activities, the committee will seek a budget of \$30,000 for the coming year. Dr. Beeckman J. Delatour, chairman of the committee, presided at the session.\*

The sum of \$600 was raised and turned over to the Peekskill Hospital on September 2 at an entertainment held at the Hebrew Community Center of Mohegan Park Association, it was reported by Morris H. Bannister, president of the Board of Directors of the Peekskill Hospital, Inc.

About 125 persons attended the benefit, which was arranged and staged by Louis Liebman and Samuel Redlick, of Mohegan. Robert E. Dempsey, a member of the Hospital Board of Directors, accepted the gift on behalf of the Peekskill Hospital.\*

Edgewood State Hospital, at Deer Park, leased to the Federal Government in June, is now ready to receive soldier patients. Situated near Mason General Hospital, Brentwood, the new unit has accommodations for 2,300 patients.

Edgewood was built by the State four years ago, but its completion was held up after the outbreak of the war, when it became certain that personnel to staff the hospital could not be found.

Under the terms of the lease the War Department will pay the State for actual expenses incurred, in addition to depreciation costs, and will restore the structure to its present condition following the termination of Army occupancy.\*

Announcement was made on September 5 by William H. Reynolds, president of the Rockaway Beach Hospital, and A. Joseph Geist, chairman of the Welfare Committee of the Hospital and vice-president of the institution, that the members of Temple Beth-El of Rockaway Park had pledged \$25,000 to the \$350,000 quota set to be raised in the current drive for the execution of a new building for the hospital.

Mr. Geist also revealed that a number of other substantial gifts and contributions have been received at the headquarters of the campaign committee for the drive located at 279 Beach 116th Street, Rockaway Park.

Mr. Geist announced that several memorial gifts have also been received to date. Under a memorial and endowment plan a \$7,300 contribution can be used for either an operating room or a delivery room memorial, \$2,500 for the cost of a men's, women's, or children's pavilion; sun porch, \$1,500; a bed, \$250. Any contributor of \$100 or more may have a bronze memorial plaque, Mr. Geist said, bearing the name of the donor or the person in whose memory the gift was made.\*

\* Asterisk indicates that item is from a local newspaper.

## FOR THE GOOD OF MANKIND

**T**HE story of Penicillin is a shining example of international cooperation for the good of mankind.

From Fleming's observations in 1929, through the pioneer work of Florey's research team, to the large-scale production of Penicillin by the American Pharmaceutical Industry, the story is one of unprecedented teamwork which has extended far beyond national boundaries.

Such cordial cooperation between

individual British and American scientists, the Rockefeller Foundation, the National Research Council, the U. S. Department of Agriculture, the War Production Board, the American Pharmaceutical Industry, and the Medical Services of the British and American Armed Forces, has never before been equaled.

Cheplin Biological Laboratories, Inc. are proud to be a member of this international team.

### CHEPLIN BIOLOGICAL LABORATORIES, INC.

(Unit of Bristol-Myers Company)

Syracuse, New York

[Continued from page 2514]

Eighty-seven Spars, the first group of women received in a Hospital Corps training school of the Coast Guard, were graduated recently at Columbia University's College of Pharmacy.

Having completed a twelve-week course in nursing and hospital laboratory procedure, the graduates will go immediately to Spar bases and marine hospitals. Many are expected to be sent overseas after approval of a bill awaiting the President's signature. \*

. . .

Air-borne armies, with perhaps the highest rate of casualties among the armed forces, will soon have a complete medical and surgical unit—the 130th Evacuation Hospital—first mobile hospital to be transported by air.

The 130th was tested for the first time in air-borne maneuvers at Camp Maskall, North Carolina, when fifty-five transports flew the entire hospital into an airfield and three hours later had it ready to handle casualties.

Parachute and air-borne troops in Normandy and Holland have had medical aid men with them who have been able to give emergency treatment, but serious cases had to be evacuated by air. Now the evacuation hospital can be flown to the wounded.

The 400-bed hospital, flown by C-47's in two echelons, can support 25,000 troops, the equivalent of three paratroop or two regular divisions.

In the hospital thirty-eight medical officers, forty nurses, and enlisted medical technicians work in six operating teams: a neurosurgical and thoracic, orthopaedic, maxillary-facial, and neurologic plastic and two general surgical teams.

Three hours after the first thirty planes land with surgeons, surgical units, eight wards, three days'

supplies, x-ray equipment, and receiving and evacuation units, the hospital is ready for operation—saving lives with immediate surgical care and relieving the air-borne troops who had been caring for the wounded. \*

. . .

Expanding opportunities for nurses after the war, especially in the public health field, were outlined on September 27 by Miss Elizabeth Phillips, assisting director of the Visiting Nurse Service of New York, at an institute preparing a group of nurses for visits to 400 colleges, where they will try to interest students in nursing careers.

Miss Phillips was one of several speakers at the first session of a four-day conference with educational and nursing leaders held at the Visiting Nurse Service headquarters under joint sponsorship of the National Nursing Council for War Service and the United States Cadet Nurse Corps.

"Returning service men who have been subjected to good health programs for a year or two will come home with changed views on medical care," she declared. "They will bring back a new appreciation of good health programs, including the immunizations which they have taken as a matter of course to give them security from disease. They will want their families to have similar good care."

Miss Mary Elizabeth Tennant, nursing fellowship adviser of the Rockefeller Foundation, pointed out that there were careers ahead in countries all over the world for a selected group of well-trained and experienced nurses. She cited those now working in South and Central America with the Office of Inter-American Affairs and those who will later be sent to liberated countries by the United Nations Relief and Rehabilitation Administration. \*

## DR. DUBLIN NAMED RED CROSS COORDINATOR

Basil O'Connor, chairman of the American Red Cross Central Committee, announced on September 20 that Dr. Louis I. Dublin, second vice-president and statistician of the Metropolitan Life Insurance Company, has been named his assistant.

Dr. Dublin's duties, Mr. O'Connor said, will include acting as coordinator of the various operating divisions of the agency and serving as liaison official between the chairman and the operating vice-chairmen. He will be on loan from Metropolitan for a limited period and will devote full time to Red Cross work.

Dr. Dublin has published many books and pamphlets on public health and on the economics of health. He has been called upon by the heads of many Federal and state agencies to make health and economic surveys and to advise on various health projects. He served in 1942 on a commission appointed by Henry L. Stimson, Secretary of War, to study the operations of the Surgeon General's Office and in 1943 made a similar study for Vice-Admiral Ross T. McIntire, Surgeon General of the Navy.

## PARALYSIS FOUNDATION ALLOCATES \$50,000 FOR FELLOWSHIPS

The National Foundation for Infantile Paralysis has announced an allocation of \$50,000 for fellowships in health education.

Under the program, developed with the United States Public Health Service, qualified men and women began in the fall nine months of academic work and three months of field experience to train them to help fight poliomyelitis.

A fellowship covers a stipend to the trainee of \$100 monthly for twelve months, tuition and university fees to the school, and expenses for field service.

A B.S. degree or its equivalent and citizenship are prerequisites for a fellowship. Women between 19 and 40 years of age and men over 30 are eligible. Applications are obtainable from the Surgeon General, United States Public Health Service, Washington 14, D. C.

Twenty-eight fellowships were awarded by the National Foundation in September.

The Public Health Service hopes to be able to give these grants again in 1945.

## REVIEWED

**Forsdike's Textbook of Gynaecology.** By J. H. Peel, B.M. Revised edition. Octavo of 440 pages, illustrated. New York, Grune & Stratton, 1944. Cloth, \$5.75.

Much smaller than the average text, this little book covers the subject very well indeed. The material is well arranged, the text is simple and clear, and the illustrations, on the whole, are excellent. The medical student and the general practitioner will like this book very much. It will answer all their questions satisfactorily and quickly.

CHARLES A. GORDON

**Manual of Human Protozoa.** By Richard R. Kudo, D.Sc. Duodecimo of 125 pages, illustrated. Springfield, Ill., Charles C Thomas, 1944. Cloth, \$2.00.

In this compact handbook of 125 pages are presented the distinguishing characteristics of the protozoa, pathogenic and nonpathogenic, which may be encountered in man. There is included with each form a brief note concerning geographic distribution of the parasite and the disease it produces. Identification is facilitated by descriptive text and beautiful hand-drawn illustrations in black and white. The technic of examining and staining is described.

The value of this manual as a ready reference handbook would probably have been enhanced if certain of the plates—particularly of malaria plasmodia and iodine-stained cysts of intestinal protozoa—could have been reproduced in color.

E. J. TIFFANY

**Technic of Electrotherapy and its Physical and Physiological Basis.** By Stafford L. Osborne, M.S., Ph.D., and Harold J. Holmquest, B.S., B.S. (M.E.). Octavo of 780 pages, illustrated. Springfield, Ill., Charles C Thomas, 1944. Cloth, \$7.50.

This is a clear and thorough presentation of a difficult subject, approached from a physical and physiologic aspect, with simplified means of treatment applications.

It is divided into four groupings: direct current, electrical muscle stimulation, thermogenic and ultraviolet radiation, high-frequency current, including a most timely and comprehensive discussion of hyperpyrexia by artificial methods.

This is a splendid work for the general practitioner and the physiotherapist.

JESSE SCHEPPS

**Cosmetology in the Negro. A Guide to Its Problems.** By Gerald A. Spencer, M.D. Duodecimo of 127 pages, illustrated. New York, Arlain Printing Co., 1944. \$2.50

In his preface the author states that this little book is the only work of its kind dealing exclusively with dermatologic conditions affecting the Negro race. Its contents comprise some eighteen chapters, a glossary of terms used, and an excellent index.

Appreciating the serious need for scientific information among the countless hosts of our colored neighbors throughout the country now engaged in the practice of cosmetology, Dr. Spencer has produced a most interesting and comprehensive exposition of

his subject which should have a large sale among those who need its help most. The book is profusely illustrated with excellent photographs and some crude but entirely satisfactory line drawings.

NATHAN T. BEERS

**Intravenous Anesthesia.** By R. Charles Adams, M.D., M.S. (Anes.). Octavo of 663 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$12.

The author has minutely reviewed the literature on intravenous anesthesia and has collated it well into one volume, which is an exhaustive treatise on this subject. Its appearance is timely, as the growing interest in this method is now reaching a peak, particularly the use of the barbiturates as anesthetics. All other agents are also considered—e.g., intravenous ether, paraldehyde, alcohol, and morphine.

The reader will find them of value, as they represent the methods of the Mayo Clinic, which pioneered and forwarded intravenous anesthesia to its present-day acceptable status. The volume is well illustrated.

F. PAUL ANSBRO

**The Medical Clinics of North America.** Boston Number. September, 1943. Octavo of 245 pages. Philadelphia, W. B. Saunders Co., 1943. Six numbers a year. Cloth, \$16 net; paper, \$12 net.

This issue of the *Clinics* contains a series of short and pithy articles, dealing with the present status of specific methods of treatment. The subjects are presented from the point of view of the individual authors rather than in the form of exhaustive reviews of the literature.

The articles entitled "The Treatment of Major and Minor Burns" by R. H. Aldrich; "The Present Status of Hormone Therapy in Gynecology" by George Van S. Smith, and "Recent Advances in Vascular Physiology and Their Therapeutic Implications" by Robert W. Wilkins should be of particular value.

ARTHUR SHAPIRO

**Medical Diagnosis. Applied Physical Diagnosis.** Edited by Roscoe L. Pullen, M.D., Quarto of 1106 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$10.

This book has attempted a well-nigh impossible task—to cover a large field of medicine in one volume of 1,100 pages, written by many contributors. The result, necessarily, is a frequently incomplete coverage of various specialties, although each contributor has exhibited an excellent knowledge of his subject and its literature. The illustrations are numerous, clear, and highly instructive. The book is splendidly gotten up and is a credit to its publishers.

MEYER A. RABINOWITZ

**Principles and Practices of Inhalational Therapy.** By Alvan L. Barach, M.D. Octavo of 315 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1944. Cloth, \$4.00.

The scientific world is greatly indebted to Dr.

[Continued from page 2518]

Alvan L. Barach for most of the recent advances in the field of inhalational therapy. All of Dr. Barach's recent contributions to this field and a complete summary of the present-day status of inhalational therapy are to be found in this excellent book.

A wealth of information, hitherto available only in scattered articles in many medical journals, is here brought together for the first time. The only suggestion that the present reviewer would make is that a chapter on the pertinent physiology of the lung might have been included early in the book. This information is, however, obtainable from the book but is scattered throughout the many chapters.

MILTON PLOTZ

**Textbook of Physiology.** By William D. Zoethout, Ph.D., and W. W. Tuttle, Ph.D. Eighth edition. Octavo of 728 pages, illustrated. St. Louis, C. V. Mosby Co., 1943. Cloth, \$4.75.

This is the eighth edition of a well-known popular text suitable for an advanced undergraduate course in physiology. The presentation is clear and concise. The figures, although a little old-fashioned, are well chosen and adequately reproduced.

The book should be useful for advanced students who wish to make a preliminary rapid survey at a more elementary level or to elementary students who are sufficiently interested to use a fairly advanced text.

ARTHUR SHAPIRO

**The Electrocardiogram. Its Interpretation and Clinical Application.** By Louis H. Sigler, M.D. Octavo of 403 pages, illustrated. New York, Grune & Stratton, 1944. Cloth, \$7.50.

Dr. Sigler is to be congratulated on having produced this excellent volume on electrocardiography.

Every aspect of the field is thoroughly covered, although obviously no effort has been made to produce a volume as encyclopedic as that of Katz.

The theoretic aspects of electrocardiography are thoroughly covered, followed by an extensive study of the electrocardiogram in various diseases of the heart and many other conditions in which the electrocardiogram may be affected. The reproductions of tracings are good and the diagrams are uniformly excellent. The style is good and the book is attractively printed and indexed. In short, the volume can be highly recommended to all. In fact, it is doubtful whether the general practitioner could purchase a more satisfactory volume at this price.

MILTON PLOTZ

**Backache and Sciatic Neuritis. Back Injuries—Deformities—Diseases—Disabilities: With Notes on the Pelvis, Neck, and Brachial Neuritis.** By Philip Lewin, M.D. Octavo of 745 pages, illustrated. Philadelphia, Lea & Febiger, 1943. Cloth, \$10.

Low-back pain has been the cause of much tribulation to every physician. This book gives an exhaustive review of the numerous causes and therapeutic procedures. The volume treats this major subject thoroughly, meticulously, and may be regarded as a reference source for the numerous complaints referable to the back which present themselves so often in every physician's office.

A. M. RABINER

**Radiation and Climatic Therapy of Chronic Pulmonary Diseases.** Edited by Edgar Mayer, M.D. Octavo of 393 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$5.00.

Dr. Mayer, together with twenty-two collaborators, each writing in his own specialized field, has produced this practical work for both the general practitioner and the specialist. The writers do not attempt to prove this type of therapy to be the only treatment, but rather try to make it applicable to practitioners who come in contact with tuberculosis in general and in specialized fields.

JOHN J. HAUFF

**Allergy in Practice.** By Samuel Feinberg, M.D. Octavo of 798 pages, illustrated. Chicago, Year Book Publishers, Inc., 1944. Cloth, \$8.00.

The entire field of allergy is covered in this excellent work. One fifth of the book is devoted to allergic rhinitis, urticaria, angioneurotic edema, atopic and contact dermatitis, allergy of the eye, and of the gastrointestinal tract. Asthma and hay fever are exhaustively presented. In addition, O. C. Durham has written a ninety-page section on pollens and pollen allergy, in which the available data on pollens, hay-fever plants, etc., is assembled. The chapter entitled "Allergy to Fungi," with its microphotographs of common allergenic fungi, is a comprehensive account of this relatively new field. Treatment is given in detail and occupies two large chapters of the book. To facilitate ready reference the experimental, theoretic and controversial material is printed in smaller type than the essential, clinical information.

This volume can be heartily recommended to both the allergist and the general practitioner.

MAX HARTEN

**A National Health Service.** By the Ministry of Health, Department of Health for Scotland. Octavo of 85 pages. New York, Macmillan Co., 1944.

This blueprint of health service projected for the people of Scotland is part of the scheme proposed by the British Parliament for the provision of the full benefits of social security to the people of the British Isles. The lack of sufficient space prevents discussion of its many controversial aspects, the most important of which are the compulsory nature of the insurance provisions and the possibility of the physician's becoming an employee of the State, both of which we in this country are, of course, completely opposed to.

It is apparent that changes in our own methods of payment, for practice, at least, are due for revision and it behooves all of us to study all plans proposed with great care and with an open mind.

BENJAMIN M. BERNSTEIN

**Rorschach's Test. I. Basic Processes.** By Samuel J. Beck, Ph.D. Octavo of 223 pages. New York, Grune & Stratton, 1944. Cloth, \$3.50.

The Rorschach's test has now achieved a definite position as a psychologic tool to be employed by psychologists as well as psychiatrists. The volume under discussion is a sequel to a previous book published by the same author in 1937.

Dr. Beck has done much to elucidate Rorschach's method and has contributed materially to publicize it. The two books by the author serve a useful purpose and are recommended to all who are interested in psychiatry.

IRVING J. SANDS

**Tuberculosis of the Ear, Nose, and Throat: Including the Larynx, the Trachea, and the Bronchi.** By Mervin C. Myerson, M.D. Octavo of 291 pages, illustrated. Springfield, Ill., Charles C Thomas, 1944. Cloth, \$5.50.

*Tuberculosis of the Ear, Nose, and Throat*, by

Myerson, is an excellent expression of a large clinical experience by the author and his associates, supplemented by a notable bibliography.

Tuberculosis in otolaryngology is uncommonly met in the usual clinic and private daily practice nowadays, and hence, because of lack of experience, is too often not properly recognized. This book should prove a valuable aid, therefore, to otolaryngologists in general, most of whom are not associated with institutions where tuberculosis is seen in its many phases

CHAS. R. WLEIH

**The Romance of Medicine. The Story of the Evolution of Medicine from Occult Practices and Primitive Times.** By Benjamin Lee Gordon, M.D. Octavo of 624 pages, illustrated Philadelphia, F. A. Davis Co., 1914. Cloth, \$5.00

Not actually a history of medicine, this book is, nonetheless, a very interesting account of the growth of medical knowledge from its roots in the dim past. Primitive medical concepts are discussed, and the persistence of many of them to the present day is pointed out. Man will always be superstitious.

The story is well told and, above all, entertaining. The binding, paper, and typography are a credit to the publisher. A good book for your library.

CHARLES A. GORDON

**The Dental Treatment of Maxillo-Facial Injuries.** By W. Kelsey Fry and others. Duodecimo of 434 pages, illustrated Philadelphia, J. B. Lippincott Co., 1944. Cloth, \$6.50

This volume is a result of the authors' experience acquired in treating maxillofacial injuries resulting from the air raids on London and from the injuries to military personnel. It is comprehensive and one of the most complete treatises of this type that I have ever had the pleasure to see. It is comprised of the subject-matter of lectures and demonstrations given to members of H. M. Forces at East Grinstead Maxillofacial Centre.

The reviewer recommends this book to all members of the dental profession who are treating maxillofacial injuries and to all plastic surgeons.

LAWRENCE J. DUNN

**The Jews and Medicine—Essays.** By Harry Friedenwald, M.D. (In two volumes.) Octavo of 817 pages, illustrated. Baltimore, Johns Hopkins Press, 1944. Cloth, \$3.75 per volume, \$7.50 per set.

In two volumes, Dr. Friedenwald presents a series of essays on the contributions of the Jewish physicians throughout the ages. The reader appreciates the scholarly and painstaking character of the chapters in these two volumes. Every educated physician should find a place for these monographs on his bookshelf.

A. M. RABINER

**The Analytical Chemistry of Industrial Poisons, Hazards and Solvents.** By Morris B. Jacobs, Ph.D. Chemical Analysis, Vol. 1. Second revised reprint. Octavo of 661 pages, illustrated. New York, Interscience Publishers, Inc., 1944. Cloth, \$7.00

The so-called "second revised reprint," after a cursory review, reveals no changes from the 1941 edition of this book. A 1944 copyright for a reprinting is misleading, giving the unwary the impression that the later copy is a new edition.

This book is still a worth-while reference work for practicing physicians, because it does list the physical effects of industrial poisons.

CHARLES SOLOMON

(Continued on page 2522)

## BLAKISTON BOOKS

### • HEWER

#### Recent Advances in Anesthesia and Analgesia—5th Edition

In this edition new material on a large number of subjects has been included. Attention is given to military aspects of the subject and 21 new illustrations are included. By C. Langton Hewer, M.B., D. A. London. 141 illus; 343 Pages; \$5.50 (1944)

### • HUGHES'

#### Practice of Medicine. 16th Edition

Hughes presents a concise survey of practical medicine incorporating the many newly recognized methods in treatment, diagnosis, vitamin therapy, etc. By Burgess Gordon, M.D., Jefferson Medical College. 36 illus; 791 Pages; \$5.75 (1942)

### • STITT-STRONG

[Continued from page 2521]

**Stop Worrying and Get Well.** By Edward Podolsky, M.D. Octavo of 124 pages. New York, Bernard Ackerman, Inc., 1944. Cloth, \$2.00.

This little book is written primarily for lay consumption. In twenty-two chapters the author tries to present the nature of worry, its influence on the human body, and how to break the habit of worrying. It is one of the many popular books that is written in a more or less didactic manner, appealing to the intelligence of human beings and hoping to improve their health. It is hardly a book that will appeal to a physician.

IRVING J. SANDS

**Sternal Puncture. A Method of Clinical and Cytological Investigation.** By A. Piney, M.D., and J. L. Hamilton-Paterson, M.D. Second edition. Octavo of 69 pages, illustrated. New York, Grune & Stratton, 1943. Cloth, \$3.50.

The statement in the preface that a second edition of this book should be called for within two years proves that it fills a real need.

This monograph will appeal principally to the specialist, but any physician desiring authoritative information concerning the interpretation of sternal marrow smears will want to read it. Those expecting to find in this procedure the solution to all their hematologic problems will soon learn that the method has only a limited field of usefulness. With only few exceptions, as the authors point out, problems that cannot be solved by careful study of the peripheral blood will still remain unsolved after study of the bone marrow.

A. S. WIENER

**The Principles and Practice of Ophthalmic Surgery.** By Edmund B. Spaeth, M.D. Third edition, thoroughly revised. Octavo of 934 pages, illustrated. Philadelphia, Lea & Febiger, 1944. Cloth, \$11.

The third edition of this inclusive work on ophthalmic surgery contains one hundred more pages than the first edition. This addition represents an expanded treatment of many subjects, but chiefly

the physiology of squint and ptosis, as well as the addition of a number of illustrations.

Although the author disclaims the attempt to make the book encyclopedic, nevertheless, within its pages will be found a description of most of the surgical procedures for diseases of the eye and its adnexa which the ophthalmic surgeon is apt to require.

With its discussion of causation and the enumeration of anticipated complications and suggestions for handling them, aptly described, and with over 500 illustrations, many of them original, to illuminate and simplify the text, this work is of enormous value to all who undertake ophthalmic surgery, and the present edition contains added material of timely interest and importance in the expanded section on traumatic conditions.

E. CLIFFORD PLACE

**Applied Dietetics. The Planning and Teaching of Normal and Therapeutic Diets.** By Frances Stern. Second edition. Quarto of 265 pages. Baltimore, Williams & Wilkins Co., 1943. Cloth, \$4.00.

This book is unique and invaluable. The author recognizes the fact that it is one thing to prepare a diet list which—on paper—completely fills the patient's needs, and quite another to make certain that the necessary diet is understood by the patient and carried out by him. When reading this book one is constantly aware of the patient as a human being, rather than as the vague recipient of the prescribed diet.

Here will be found a list of factors other than food which influence diet: income and expenditure, nationality, education, food within and outside the home, sleep and rest, body cleanliness, occupation, and the daily regimen, etc. Concrete suggestions for teaching diet are given. The section on dietary outlines to meet special conditions lists not only the foods to be taken, but other important related facts, such as the physiology of each condition, its abnormal aspects, contributing factors, laboratory data, etc. This book is highly recommended.

## MEDICAL EXPEDITION TO THE LIBERATED NETHERLANDS

A group of prominent physicians recruited from American medical schools and hospitals will leave for Holland after that country's liberation, to give a series of four-week postgraduate refresher courses in Dutch universities, which will be found sadly disorganized by four years of Nazi occupation. This plan was announced by Dr. Herbert Loeb, of Cambridge, Massachusetts, former president of the Netherlands Dental Association at Amsterdam, who was instrumental in arranging for a similar postwar movement to bring dental care to the Netherlands. Of this latter movement, known by the name of "Ivory Cross Expedition," details were released by the Netherlands Information Bureau a few weeks ago.

Nine medical specialists will make the transatlantic voyage to give the refresher courses which

Amsterdam, where he specialized in neurology and psychiatry for the Dutch branch of the Rockefeller Foundation. He discussed his plan with Dr. Gerrit Bolkestein, Netherlands Minister of Education, when the latter toured a number of American universities last May. It found the general approval of the Minister, and details were subsequently worked out.

The Netherlands government will finance the traveling and other personal expenses of the American professors, who will, however, receive no extra or special compensation for their work in Holland. Because of German looting of Dutch medical school and hospital equipment, the physicians will take with them all material and instruments needed for

... will  
surgery; Dr. Smith, bacteriology and infectious

Snapper, director of the Department of Graduate Medical Education at Mount Sinai Hospital, in New York City. He left the University of Amsterdam in 1937 to go to the Rockefeller Foundation at Peking, China. He was captured by the Japanese and later sent to America as an exchange prisoner.

Completing the roster are Dr. Van Slyke, of the Rockefeller Institute of New York City, for biochemistry, and Dr. Marshall, of Johns Hopkins University, for physiology and pharmacology.—  
Release from the Netherlands Information Bureau, July 19, 1944

VI-FERRIN Lederle furnishes iron in one of its most effective forms, ferrous sulfate, together with liver and vitamin B factors. Capsules are tasteless and cannot discolor teeth.

Iron-deficient anemias frequently occur in association with vitamin B deficiency and the combination of liver and iron has been found exceptionally effective for rapid hemoglobin regeneration. VI-FERRIN Lederle is indicated for the treatment of iron-deficient anemias and for the prevention of such nutritional anemias.

### VI-FERRIN Lederle PROVIDES

	Each Capsule	Each Tablet
Dried Ferrous Sulfate.....	0.2 Gm.	0.2 Gm.
Thiamine HCL (B <sub>1</sub> ).....	0.25 mg.	0.25 mg.
Riboflavin (B <sub>2</sub> ).....	0.19 mg.	0.35 mg.
Niacinamide.....	2.5 mg.	2.5 mg.
Pantothenic Acid.....	0.4 mg.	1.0 mg.
Choline.....	10 mg.	4 mg.

Full daily dosage will contain total unfractionated aqueous extract derived from 30 Gm. (Tablets) or 54 Gm. (Capsules) of whole liver.

Reap  
the  
Ill  
Wind.

"It's an ill wind that blows no good," the old proverb declares. And the genius of medical men is giving new meaning to these old words.

For in the ill wind, the shattering, terrible wind of war, they are finding new facts . . . developing new skills . . . improvising new techniques . . . reaping new knowledge that will play a vast, important part in the building of that "better world to come."

**THE SODALINE**  
*Brewer*  
The ORIGINAL ENTERIC-COATED TABLET  
OF THEOBROMINE SODIUM ACETATE  
**EFFECTIVE**  
in Coronary Artery Disease and Edema

Clinical experience and carefully controlled studies in humans have definitely proven the value of Theobromine Sodium Acetate in treating certain Cardiovascular and Renal diseases, and the value of the enteric coating in permitting adequate dosage without causing gastric distress.

Supplied—in 7½ grains with and without Phenobarbital ½ grain; in 5 grains with Potassium Iodide 2 grains and Phenobarbital ¼ grain (cost approximately \$1.50 per bottle of 100 tablets); and in 3¾ grains with and without Phenobarbital ¼ grain (cost approximately \$1.00 per bottle of 100). Capsules, not enteric coated, are available in the same potencies for supplementary medication.

\*Literature giving confirming bibliography, and physicians samples will be furnished on request.

## IN MILK DIETS

**W**hether human or cow's milk constitutes the basis of the average diet of early infancy, a deficiency of certain vitamin B factors can be looked upon as a natural corollary.<sup>1,2</sup>

White's Multi-Beta Liquid is specifically formulated to reinforce such diets—supplying the major B factors, in drop dosage, in amounts proportionate to average dietary insufficiency. Routine administration of five drops or more daily assures the infant an optimal supply of all clinically important B vitamins.

White's Multi-Beta Liquid is also a sound and economical supplement to such restricted adult diets as the Sippy and Karell regimes, or others based on milk diet. It is of value, too, when difficulty in swallowing tablets or capsules is encountered or when tube feeding is necessary.

*simple depression*

*"... the most favorable of all disorders  
for benzedrine therapy."\**

In simple depression, Benzedrine Sulfate therapy may be expected to benefit the patient by breaking the strangle-hold of pathologically organized habit-patterns and by restoring what Myerson calls the patient's "energy feeling".

The following instances of simple depression are familiar to every physician:—

1. Depression following acute infectious disease, typically influenza.
2. Depression following surgical operations.
3. Depression following pregnancy and childbirth.

4. Depression accompanying the onset and course of the menopause in women and the involution period in men.

5. Depression associated with menstrual dysfunction.

6. Reactive depression precipitated by an external problem situation which the patient can neither resolve, tolerate, nor ignore.

# CĒPACOL

*answers this question in throat medication*

You wouldn't expect your patient to hold a solution in the mouth or gargle continuously for 5 minutes. Yet the standard test for an antiseptic solution requires only that it be effective in this length of time.

## CĒPACOL

Brand of Alkaline Germicidal Solution

### FOR THE INFLAMED THROAT

Cēpacol, which contains the powerful non-mercurial germicide Ceepryn (brand of cetylpyridinium chloride), has been shown by standard antiseptic tests to destroy most pathogenic bacteria common to the mouth and throat *within 15 seconds after contact.*

Other outstanding characteristics of Cēpacol are its freedom from toxicity, lack of irritation, its alkalinity, penetration, and foaming detergency.

Used as spray or gargle, Cēpacol has a delightful, refreshing flavor. Available at prescription pharmacies in pints and gallons.

# PENICILLIN-C.S.C.

Unretouched photo of refrigerator car  
being loaded with Penicillin C.S.C.

## A FULL-CARLOAD SHIPMENT OF PENICILLIN

This shipment of Penicillin-C.S.C. to the armed forces demonstrates the tremendous growth of production here at the Commercial Solvents Corporation penicillin plant. Billions upon billions of units of Penicillin-C.S.C. are constantly being shipped to every corner of the globe, wherever Americans are waging the fight for a better, safer future. Part of that better future will be the potent weapon which Penicillin-C.S.C. provides in the physician's fight against disease.

# For The Armed Forces

WHETHER penicillin will be released for broad civilian practice tomorrow or on some more distant day, adequate distribution facilities for Penicillin-C.S.C. have been arranged. It will be available in every part of the United States, in amply stocked depots, to supply the needs of every physician, every hospital. For office practice and for administration in the patient's home, it will be available in combination packages providing two rubber-stoppered, serum-type vials, one containing 100,000 Oxford Units of Penicillin-C.S.C., the other permitting the withdrawal of 20 cubic centimeters of pyrogen-free physiologic salt solution in which the penicillin is to be dissolved.

# Visual aid for differentiation in ARTHRITIS DIAGNOSIS

"THE HANDS IN ARTHRITIS"—a book of color photographs selected from thousands of cases of chronic arthritis—has been prepared by the Medical Department of Nutrition Research Laboratories—manufacturers of ERTRON\*.

Much valuable diagnostic history can be obtained from the arthritic hand—hence the various etio-logic groups of arthritis are illustrated and described as they affect the hands.

To assist the physician in diagnosing the type of arthritis so that corrective treatment may be instituted, this graphic book has been mailed to the entire medical profession. If you desire additional copies please write to the Medical Department of Nutrition Research Laboratories, 4210 Peterson Avenue, Chicago 30, Illinois.

## NUTRITION RESEARCH LABORATORIES CHICAGO

\*Trademark Reg U S.  
Pat. Off.

ERTRON is a trademark of Nutrition Research Laboratories, Chicago, Illinois. It is a registered trademark in the United States and in many other countries. ERTRON is a synthetic product which is chemically identical to the natural product found in the human body. It is a powerful antioxidant and is used in the treatment of various conditions, including arthritis, heart disease, and cancer. ERTRON is also used in the food and drug industries as a preservative and flavoring agent. It is a safe and effective product which has been used for many years.

# NOW FOREIGN-BODY LOCALIZATION with the aid of SOUND

● Today the surgeon need not grope for a metallic foreign body...need not guess. The Berman Metal Locator *equipped with sound* makes the removal of a metallic foreign body an operation that can be consummated in a matter of minutes. With the sound equipped Locator, an audible note of increasing pitch signals the approach of the probe to the metallic foreign body. The sound signal provides pin point localization at the operating table during the entire progress of the operation.

Clinical experience with the armed forces and in numerous leading hospitals\* throughout the country has shown the Berman Metal Locator to be as "INDISPENSABLE AS X-RAY."

It makes failure practically impossible; removal of foreign body usually a matter of minutes; greatly minimizes trauma.

Described in Journal of A. M. A., Jan. 9, 1943, vol. 121, pp. 123-125; American Journal of Surgery, Sept. 1944, vol. LX5 No. 3, pp. 373-380; Archives of Ophthalmology, Mar. 1944, vol. 31, pp. 207-210.

\*Operations performed with the aid of Locator and operator lent by Waugh Laboratories.

Write for this descriptive booklet, prices and delivery dates, on your letterhead.

*Trifles make perfection,  
and perfection is no trifle!*

Michelangelo

This was the creed of Michelangelo. Trifles—menial tasks and lesser elements of precision—always merited his most careful personal attention in his constant aim for perfection.

Similarly, the pharmaceutical chemist has exercised meticulous care and scientific precision in the complex manufacture of the organic iron preparation, Arsenoferratose Elixir. Skillful blending of selected ingredients and diligent attention to numerous so-called "trifles" have contributed to produce its superb palatability and perennial efficiency. Indeed, in the minds of many physicians, Arsenoferratose Elixir is "the iron tonic of perfection" for all those anemias known to be benefited by iron therapy.

Supply Arsenoferratose Elixir, Arsenoferratose Elixir with Copper, and Ferratose Elixir, are supplied in bottles of 8 fluid ounces. Also economical pint bottles.

Dosage: 1 to 3 teaspoonfuls, 2 or 3 times daily, according to age and requirements.

*Literature and samples on request*

HEMATINIC and ALTERATIVE

RARE CHEMICALS, INCORPORATED, HARRISON, NEW JERSEY

# Paredrine-Sulfathiazole

**How It Shortens the Course of Infection  
and Helps Avert Sequelae to Cold**

**T**HESE drawings—from photographs presented as a scientific exhibit at the 1944 Meeting of the American Academy of Ophthalmology and Otolaryngology—demonstrate why Paredrine-Sulfathiazole Suspension is so strikingly effective in nasal and sinus infections. The choanae of patient T. D.—with subacute pansinusitis—are illustrated.

The dramatic success of Paredrine-Sulfathiazole Suspension in aborting colds and averting complications is largely due to its prolonged bacteriostatic action. When the Suspension is administered on retiring, for example, sulfathiazole can often be observed on infected mucosa the next morning—conclusive evidence that bacteriostasis has persisted all night long.

The fundamental reason for this prolonged bacteriostatic action is the fact that Paredrine-Sulfathiazole Suspension—not a solution, but *a suspension* of free sulfathiazole—covers the nasal mucosa with a fine, even frosting of sulfathiazole, which does not quickly wash away. Yet the Suspension does not cake or clump, and does not interfere with normal ciliary action.

---

**SMITH, KLINE & FRENCH LABORATORIES'**  
**VASOCONSTRICTOR - SULFONAMIDE**

---

# suspension —

## ◀ 30 MINUTES AFTER INSTILLATION

The Suspension has been swept onto infected areas, where ciliary action is impaired. The sulfathiazole remains on infected areas and keeps producing a bacteriostatic solution.

## 45 MINUTES AFTER INSTILLATION ▶

Sulfathiazole mixed with pus is passing over the orifice of the Eustachian tube. Should pus enter the middle ear, the sulfathiazole will minimize the likelihood of otitis media.

## ◀ 50 MINUTES AFTER INSTILLATION

Sulfathiazole is streaming beneath the turbinates where it mixes with pus draining from the sinuses. Thus, the Suspension helps prevent the incidence of nasopharyngitis, pharyngitis, etc.

Announcing

**Desenex**

A *Specific* for the  
**Superficial Fungous Infection**  
**ATHLETE'S FOOT**

Desenex, a new development of the widespread war research, represents the successful therapeutic application of fatty acids for the treatment of this prevalent and stubborn condition.

The active ingredient of Desenex is undecylenic acid. This unsaturated fatty acid is as harmless to the skin as stearic acid, which is widely used in cosmetics. Surprisingly, however, this generally inert substance is as *specific and potent in its action on fungi* as some widely used chemotherapeutic agents are on other organisms.

Desenex may be used with confidence. Clinical cure of the troublesome fungous infection—athlete's foot—is generally achieved within a relatively short time by daily application of Desenex.

# IN IMPAIRED FAT DIGESTION

Degalol, the original chemically pure deoxycholic acid, is the constituent of human bile which is chiefly concerned with the emulsification of ingested fats.

When bile secretion is deficient, or totally lacking as in biliary fistula, the administration of Degalol assures not only digestion and

absorption of food fats but also of the fat-soluble vitamins A, D, E, and K.

When fatty foods prove intolerable in the absence of cholecystic pathology, Degalol usually relieves the postprandial distress and permits of liberalization of the diet.

Supplied in boxes of 100 1½ grain tablets.

Riedel - de Haen, Inc., New York 13, N. Y.

# Restores Vaginal pH Destroys the Pathogenic Flora

## Vaginal pH Chart

In vaginal leukorrhea, Floraquin provides destruction of the pathogenic organisms and promotes rehabilitation of the vaginal mucous membrane. Containing the non-toxic protozoacide, Diodoquin, together with lactose and dextrose, this product of Searle Research removes the causative factors of leukorrhea and restores normal vaginal physiology.

Floraquin brings about the establishment and maintenance of an acidity (pH 4.0) unfavorable to vaginal infections. Its lactose and dextrose provide the necessary substrate for the production of lactic acid, a condition which enhances destruction of pathogenic organisms and promotes normal flora—Doderlein's Bacillus.

*For Office Insufflation*—Floraquin Powder in bottles of 1 oz. and 8 oz.

*For Home Routine*—Floraquin Tablets in boxes of 24.

## A TANDEM ACTION in Gastro-Intestinal Dysfunction

**Zymenol** Assures normal intestinal content through  
brewers yeast enzymatic action.\*

Aids restoration of normal intestinal motility  
with complete natural vitamin B Complex.\*

This two fold natural therapy is equally effective in the irri-  
table, unstable or stagnant bowel without catharsis, artificial  
bulkage, large doses of mineral oil or constipating astringents

*Economical teaspoon dosage avoids leakage*

# THROAT CHEMOTHERAPY WITHOUT SYSTEMIC TOXICITY

**T**HE unique value of this new, effective method for the local treatment of certain throat infections consists in this:

1. Chewing one tablet for as long as one hour provides a *high* salivary concentration (averaging 70 mg. per cent) of dissolved sulfathiazole...
2. that is *maintained* in immediate and prolonged contact with oropharyngeal areas which are not similarly reached by gargles or irrigations...
3. yet relatively small amounts of the drug are ingested, and even with maxi-

mal dosage, blood levels are negligible—for the most part not even quantitatively measurable.

**INDICATIONS:** Acute tonsillitis and pharyngitis, septic sore throat, infectious gingivitis and stomatitis caused by sulfonamide-susceptible micro-organisms. Also indicated in Vincent's disease and in the prevention of local infection secondary to oral and pharyngeal surgery.

Supplied in boxes of 24 tablets, sanitized in slip-sleeve prescription boxes—on prescription only.

## Thantis Season

Winter time is the season of throat affections. Crowded transportation facilities, due to wartime conditions, cause exposure of more people to infection.

Many physicians have found Thantis Lozenges to be effective in relieving throat soreness and irritation, because they are antiseptic and anesthetic for the mucous membranes of the throat and mouth.

Thantis Lozenges contain Merodicein (H. W. & D. Brand of Diiodooxymercuriresorcinolsulfonphthalein-sodium), 1/8 grain, and Saligenin (Orthohydroxybenzylalcohol, H. W. & D.), 1 grain. They are effective and convenient; they dissolve slowly, permitting prolonged medication.

Thantis Lozenges are supplied in vials of twelve lozenges each.

# A decade of Vitamin Leadership

For a decade—since 1934, when Ascorbic Acid was synthesized—the name Merck has been identified with leadership in the synthesis, development, and large-scale production of pure vitamins.

The following list of contributions in the vitamin field made by Merck chemists and their collaborators emphasizes the outstanding rôle played by Merck & Co., Inc. in the development of these vitally important substances.

## 1934

Ascorbic Acid Merck (U.S.P.) was made available by Merck & Co., Inc.

## 1936

Vitamin B<sub>1</sub> was synthesized in the Merck Research Laboratories.

## 1937

Thiamine Hydrochloride Merck (U.S.P.) was made available in commercial quantities.

## 1938

Nicotinic Acid Merck (U.S.P.) (Niacin) and Nicotinamide Merck (U.S.P.) (Niacinamide) were made commercially available.

## 1938

Riboflavin Merck (U.S.P.) was the second pure crystalline vitamin to reach commercial production during that year.

## 1938

Alpha-Tocopherol (Vitamin E) was identified and synthesized by Merck chemists and their collaborators in other laboratories.

## 1939

Vitamin B<sub>6</sub> was synthesized in the Merck Research Laboratories.

## 1940

Vitamin B<sub>6</sub> Hydrochloride Merck (Pyridoxine Hydrochloride) became available in commercial quantities.

## 1940

Alpha-Tocopherol Merck (Vitamin E) was made commercially available.

## 1940

Vitamin K<sub>1</sub> Merck (2-Methyl-3-Phtyl-1,4-Naphthoquinone) was made commercially available.

## 1940

Menadione Merck (U.S.P.) (2-Methyl-1,4-Naphthoquinone), a pure chemical having marked Vitamin K activity, became available in commercial quantities.

## 1940

Pantothenic Acid, member of the Vitamin B-Complex, was identified and synthesized by Merck chemists and their collaborators in other laboratories.

## 1940

Calcium Pantothenate Dextro-rotatory, a biologically active form of Pantothenic Acid, was made commercially available by Merck & Co., Inc.

## 1943

Biotin, member of the Vitamin B-Complex, was synthesized in the Merck Research Laboratories.

## 1944

Biotin Merck was made commercially available by Merck & Co., Inc.

Merck & Co., Inc. now manufactures all the vitamins commercially available in pure form, with the exception of vitamins A and D.

**MERCK & CO., Inc.** *Manufacturing Chemists* **RAHWAY, N. J.**

'GELUSIL'\* Antacid Adsorbent is a wish fulfilled in peptic ulcer therapy. It contains an alumina gel which is non-reactive with gastric hydrochloric acid and does not break down, as do ordinary gels, into astringent, constipating aluminum chloride. 'GELUSIL' Antacid Adsorbent not only forms a colloidal shield protecting the inflamed peptic ulcer area, but effectively inactivates excess proteolytic pepsin. Through magnesium trisilicate, uniformly dispersed in its gel phase, 'GELUSIL' Antacid Adsorbent exerts a powerful and prolonged antacid-adsorbent antipeptic action.

Thus, within minutes, 'GELUSIL' Antacid Adsorbent provides relief which lasts for hours...Supplied in bottles of 6 and 12 fluidounces, and in boxes of 50 and 100 cellophane wrapped tablets. \*Trademark Reg. U. S. Pat. Off.

WILLIAM R. WARNER & CO., INC., 113 WEST 18TH ST., NEW YORK 11, N. Y.

**'GELUSIL'**  
antacid adsorbent

SULFATHIAZOLE in micro-crystalline form for maximum contact with infected areas.

EPHEDRINE for prompt, prolonged shrinkage of congested nasal mucous membranes.

ISOTONIC with nasal secretions.

pH ADJUSTED to the slightly acid range of normal nasal secretions.

AQUEOUS, soothing base, readily miscible with nasal secretions.

5

## OUTSTANDING FACTORS for EFFECTIVE NASAL RELIEF

Strikingly effective in the relief of the common cold and acute or chronic sinusitis, GLUCO-FEDRIN\* with SULFATHIAZOLE is in accord with modern medical thinking.

Various investigators have reported the value of the intranasal application of sulfathiazole in very finely divided form. Others have pointed out the advantage of the collateral use of ephedrine to increase nasal airway

occluded by congestion and to promote sinus drainage. The desirability of isotonicity, pH adjustment, and the use of an aqueous vehicle have been widely discussed and are quite generally accepted today.

These five factors are combined in the formula of GLUCO-FEDRIN with SULFATHIAZOLE. It is applied by spray, applicator, pack or dropper. Supplied in bottles of one ounce.

\*Trade Mark Reg. U. S. Pat. Off

### GLUCO-FEDRIN with SULFATHIAZOLE

*Parke, Davis & Company, Detroit 32, Michigan*

# IN B COMPLEX DEFICIENCY

The general need for vitamin supplementation is increasing. The average diet is often so close to the borderline of B complex sufficiency, that subclinical deficiencies always must be considered.

FORTIPLEX meets the need for speedy and complete satisfaction of the daily B complex requirement and for the replenishing of depleted stores, even under unfavorable conditions.

Not only because of its rational formula, but also because of its notably reasonable price, FORTIPLEX merits the preference it is being given by a constantly growing number of physicians.

Each tablet is standardized to contain not less than:

Thiamine Hydrochloride	..5.0 mg.
Riboflavin	.....5.0 mg.
Pyridoxine Hydrochloride	1.0 mg.
Calcium Pantothenate	..1.0 mg.
Niacinamide	.....20.0 mg.

Plus all the other factors supplied by the yeast and liver concentrate base.

### What Can Be Done?

It is becoming apparent that the increasing load upon the shoulders of civilian medical practitioners is reaching a somewhat dangerous point. This year should mark the beginning of the really tough sledding for most physicians. No replacements for civilian doctors who become ill or die seem to be possible. Even in the event of a German defeat

ers will return to  
or more service  
of Germany.

"While it is not possible to obtain any official statement concerning plans for the release of military doctors, unofficial talks with War and Navy Department personnel clearly indicate that no important discharge of medical officers can be expected, in any branch of service, until after Japan has been defeated.

"The Army has never filled its original quota of one doctor for every 100 to 125 soldiers. Now, it is pointed out, the desired doctor-soldier ratio can be more nearly attained, and the care and rehabilitation of casualties facilitated, by retaining in service the 5,000 or more medical officers serving those troops scheduled for demobilization.

"Even if Army medical needs can thus be satisfied, discharge of physicians will still proceed slowly because of the difficulty of obtaining replacements.

In announcing its demobilization plan, the War Department said: 'Regardless of a man's priority, certain types of personnel can never become surplus as long as the war with Japan continues.' Doctors working in such fields as neurosurgery, plastic surgery, and psychiatry, for example, can probably expect to remain in service until the war in the Pacific has been won.

"Army medical men eventually discharged as surplus will, for some time to come, find their services much in demand by the Navy, which will not reach its peak strength until July. Naval needs can be only partly met by drawing on the 6,000-odd medical students in its V-12 program. A spokesman for the Bureau of Medicine and Surgery, emphasizing the Navy's need for doctors, said: 'The Navy would be glad to consider for commissioning any medical officer discharged by the Army.'"

In a communication to this JOURNAL, Lt. Col. Harold C. Lueth, MC, Army Service Forces, says

"Community medical care in the future will undoubtedly be impaired unless additional replacements are found for the losses of civilian practitioners. Any replacement scheme will, of course, depend upon the number and speed at which medical officers are discharged or released from active military duty. This problem, like the first one, has not

<sup>1</sup> Medical Economics, Oct., 1944.

been definitely decided and must await future developments."

In addition, the withdrawal of nurses for the armed forces is operating to require more of the doctor's time, to complete his hospital work. And the inability of the hospitals to care for many people is increasing the necessity for house calls, home care of illness, and putting a still further drain on physicians' energy and time.

Apparently, little relief can be anticipated in the near future, from any of the ordinary sources of replacement.

It seems timely, therefore, to consider what might be done, not by choice but of necessity, to meet the situation, to make the present physician population last a little longer and to extend its services to more people.

First, there is the matter of meetings. Committee work of the various societies is still far too heavy, and prolonged. It is shared by too few men. Night meetings cut into time for rest, which is becoming more and more a necessity. Something can be done about that.

If rest is a necessity, relaxation is even more imperative. It is something few physicians ever enjoy. If a physician is at

home, the telephone prevents it effectively; if he is away from home, then worry over the case that is not doing too well shatters it. There is no escape from the prison of responsibility, individual responsibility, responsibility that sends blood pressure up, and which drives inexorably. Can anything be done about that? We doubt it. Except that group practice in some measure provides a kind of relief by providing opportunity for more frequent consultation, and thus a sharing to some extent of responsibility. In some places night calls are handled through the local hospitals and thus a measure of relief is afforded by a better distribution of this particular responsibility. These matters are here brought up in the hope of directing the ingenuity of the profession to the possible expedients, which may avoid needless drains on definitely limited energy and time, without sacrifice of quality of services.

Many possible expedients have not yet been fully explored, probably because the necessity for them has seemed somewhat remote. But the time appears to be fast approaching when they must be considered locally, throughout the state, and nationally. It is better to begin too soon than too late.

## Appendicitis

In a letter to the JOURNAL, Dr. Donald B. Armstrong of the Metropolitan Life Insurance Company, says, in part:

"We are asking our Field Staff to place copies of our 'Appendicitis' leaflet in insured and other homes in their communities. We expect to reach approximately 600,000 families. This distribution will serve as a follow-up of an advertisement on appendicitis which the Company carried during June in such magazines as the following: *Saturday Evening Post*, *Collier's*, *Time*, *Newsweek*, *Ladies' Home Journal*, etc. These magazines have a combined circulation of more than 30,000,000. An appendicitis poster was recently displayed in a large number of plants and offices carrying group insurance. Additional copies of the poster will be displayed by agents at this time. . . ."

Many will doubtless have seen these clear, concise, advertisements and posters. Their message is simple: "Don't take a laxative, food, or medicine! Call your doctor immediately. Rest quietly."

The completeness and simplicity of these instructions, with their illustrative drawings, seem to us to be the way a public health campaign should be conducted.

In this regard, and by study of such campaigns as this, much valuable information could be gleaned as to possible ways to forward the plans for voluntary prepayment medical insurance.

The follow-up leaflet now being distributed is also worthy of comment. It describes what appendicitis is, when to suspect it, what to do and what to avoid, and what to remember. Under this last heading we find:

"A study of appendicitis made in a large Eastern city shows that:

When Appendicitis Patients

Took—

No laxative.....Only 1 in 62 died

One laxative.....1 in 19 died

More than one laxative.....1 in 9 died  
 When Appendicitis Patients Went to the Hos-  
 pital—  
 Within 24 hours.....Only 1 in 61 died  
 Within 48 hours.....1 in 24 died  
 Within 72 hours.....1 in 17 died  
 After 72 hours.....1 in 13 died"

Here, we submit, is something people can understand. It has undoubtedly already contributed much and will continue to contribute to the reduction in mortality from this cause.

Medicine would do well to study this material. Undoubtedly medical expense insurance would do much toward obtaining for many people early diagnosis, as hospital insurance has doubtless assisted many to

obtain, early operation when necessary. Therefore, medicine's sponsorship of medical care insurance would make more effective any campaign of this sort.

We are handicapped in our title. Appendicitis is short and simple, easily understood, arresting. "Voluntary medical expense indemnity insurance" is not. It seems that a short, arresting name for this kind of insurance would be a productive first step to capture public and professional interest.

We would then be in a position to follow up such forward-looking public health work as is illustrated by the life insurance companies' posters, advertisements, and leaflets.

## Horace Wells Centenary in Hartford, December 11

The Horace Wells Centenary, which has been marked throughout the nation by dental societies during the present year, will be brought to a close December 11 with an elaborate program at Hartford, Connecticut, in which dental, medical, and civic groups will participate. The program is under the direction of the Horace Wells Centenary Committee, of which Eugene M. Clifford, Hartford, is chairman.

Because of wartime transportation difficulties it has not been possible to schedule a national meeting to mark the centennial as originally planned, but the Committee urges all dental schools, component and constituent societies to mark the anniversary locally December 11 with appropriate ceremonies.

At the recent meeting of the American Dental Association in Chicago, Tuesday, October 17,

was officially designated as "Horace Wells Day" and a ceremonial was held preceding the third meeting of the House of Delegates.

During the past year several resolutions have been passed to commemorate the centennial. The Connecticut State Legislature in a special session January 28, 1944, passed a resolution on Horace Wells. The American Medical Association, at its recent annual meeting, approved a resolution which "commends and endorses the celebration during 1944 of the centenary of this application of nitrous oxide anesthesia by Dr. Horace Wells of Hartford, Connecticut." The Anesthesiology Section of the American Medical Association also passed a similar resolution. A joint resolution memorializing the name of Horace Wells was recently passed by the U.S. Senate.

## Correspondence

November 2, 1944

To the Editor:

r 15, 1944,

r. Harrison

"Thorough study of the therapy of this condition. I devoted seventeen years to this work. During these years of study and research I read almost every article on bursitis, beginning with the days of Codman, and I am still

interested in every article on this subject. Naturally I read the paper of Dr. McLaughlin most carefully, and I wish to say a few words about it.

The article is wonderfully written. The pathology is pictured so vividly that no Rembrandt could have done better. Reading it you imagine that you are with Dr. McLaughlin at the surgical table, where you actually see him using his scalpel with the utmost skill, displaying before you details in anatomy and pathology. In this manner my illusions carried me throughout the article, until

I came to the paragraph on "Therapy." Here I, somehow, became disillusioned, because of the kind of treatment it advocates.

Says the paragraph: "There are only two forms of therapy . . . having proved curative effects—opening the deposits by knife or needle." I wish to suggest that both these methods be discarded as often as possible. The former is at times risky, and the latter is very torturous. Indeed, physicians and lay patients alike who were treated by needling unsuccessfully or with aggravation of their bursitis and then came to me for treatment have complained most bitterly of that torture. Besides, the results are meager. Dr. McLaughlin himself states that permanent relief was obtained "in less than 25 per cent of all such cases"; Dr. Bosworth, who had great experience in the therapy of bursitis, says that needling is less certain than the scalpel. With reference to the latter, I wish to state that I know of cases that suffered pain in the shoulder for many years after the operation, and I have seen shoulders operated upon in the best hospitals resulting in the loss of function forever. It is because of such mishaps that the noble and humane surgeon, Dr. Codman, voiced his protest against surgery in calcified bursitis.

Today physical medicine offers a definite, safe, and painless method for the cure of this malady in over 95 per cent of the cases. Of course, the physical therapy which I have in mind is not baking and massage or short-wave diathermy. We have studied so thoroughly the behavior of the various

apparatus we have employed in our research that we know exactly their effect on symptoms and pathology. This is probably the reason for our success.

In 1936, the April 1 issue, a preliminary report of my researches in bursitis at the Mount Sinai Hospital Physical Therapy Clinic appeared in the *NEW YORK STATE JOURNAL OF MEDICINE*. I then received letters of interest and request for reprints, from almost every English-speaking corner of the earth, even from South Africa. I was surprised to see that the *JOURNAL* reached so far and was so widely read. When Lord Horder and his staff came from England to see the American doctors at work they had me, too, on their list.

All the years after the preliminary report was published I kept on improving on the methods, and in November, 1943, I published a final report in the *Medical Record* under the following title: "The Nonsurgical Treatment of Calcified Bursitis—A Definite, Safe, and Painless Method." This time, too, I received letters from practically every state in the Union, and many editors have reviewed the article in their journals—e.g., *Archives of Surgery*; *Quarterly Review of Medicine*; *Mount Sinai Hospital Journal*, etc. Thus I feel confident that American physical medicine can offer a definite, safe, and painless cure for "calcified bursitis."

## 1945 ANNUAL MEETING

Medical Society of the State of New York

*The 139th Annual Meeting of the Medical Society of the State of New York will be held Monday, April 30, to Thursday, May 3, 1945, inclusive, at the Hotel Statler in Buffalo.*

COUNCIL COMMITTEE ON CONVENTION

# *Symposium: Intensive Treatment of Syphilis*

## RAPID PLAN FOR TREATMENT OF EARLY SYPHILIS FOR OFFICE PRACTICE

A. BENSON CANNON, M.D., JEROME K. FISHER, M.D., and LOUIS WEXLER, M.D.,  
New York City

IT IS the general practitioner who has in the past treated the majority of the cases of syphilis, and he will in all likelihood continue to do so in the years to come. Therefore, any scheme of treatment must of necessity be devised primarily for his use, leaving to the syphilologists the more complicated and specialized procedures that are necessary for handling the more difficult therapeutic problems which may arise in the management of cases of syphilis.

In order to fit the general practitioner into the intensive-treatment program of syphilis we have undertaken to present, with the prospect of a high percentage of cures, a plan of treatment for the patient with early syphilis that can be accomplished from within a few weeks to several months and yet be relatively safe and inexpensive.

As a result of our study in intensive treatment on 332 patients with early syphilis at Presbyterian Hospital in New York City (using a minimum of 3.0 Gm. of arsphenamine by the syringe method four times daily for six days) we are convinced of the need for a more practical, a simpler, safer, and cheaper treatment that will meet the needs of the ambulatory patient with syphilis. The knowledge gained by this experimental study combined with the experience of other observers using various plans of therapy has served as a basis for our study of an intensive treatment suitable for office patients with early syphilis.

### Résumé

At this time it might be well for us to review the work of others in their attempts at a rapid cure of early syphilis.

Massive dosage in the treatment of syphilis, as we all know, is no new thing. It has long been an accepted fact among most syphilologists that the more arsenic one was able to give in early syphilis without producing damage, the better were the prospects of cure. Ehrlich himself promulgated the theory of the single sterilizing dose as the desired goal in the treatment of syphilis, and there was much experimentation with various time-dose schedules and different

routes of administration by his contemporaries and followers.

Scholtz,<sup>1</sup> a contemporary and collaborator of Ehrlich, is believed to have been the first to have tried to treat syphilis in human beings with massive doses of arsphenamine injected intravenously. He gave a total of 0.9 Gm. to 1 Gm. in at least three or sometimes four injections on two successive days (0.3 Gm. at 9:00 A.M. and 0.2 Gm. at noon the first day; the second day 0.2 or 0.25 Gm. at 9:00 A.M. and 0.15 or 0.2 Gm. at noon). He reported good clinical and serologic results. After a two-and-one-half-year trial, he found that most of his patients were entirely free from clinical symptoms, and that the blood Wassermann had remained negative since a short time after completion of treatment.

Pollitzer<sup>2</sup> (1916) also favored massive divided doses of an arsenical in the treatment of early syphilis. He gave three daily injections of arsphenamine, 0.5, 0.5, and 0.4 Gm. respectively, followed by four to six weekly injections of mercury salicylate.

In 1921 Lueth<sup>3</sup> advocated the giving of a total of 2.55 Gm. of neoarsphenamine in four days. On the first day he gave 0.3 Gm. of neoarsphenamine and an injection of mercury on the second and third days, 0.45 Gm. of neoarsphenamine plus mercury both morning and evening. On the morning of the fourth day he gave the sixth dose of 0.45 Gm. neoarsphenamine plus mercury. The patients were discharged on the fourth day, showing much clinical improvement and with the cures far advanced.

Schreus (1926)<sup>4</sup> tried giving neoarsphenamine in doses of 0.3 Gm. followed by 0.15 Gm. at fifteen-minute intervals until a total of 0.75 Gm. had been administered, or an initial dose of 0.45 Gm. followed by 0.3 Gm. at twenty- to twenty-five-minute intervals until a total of 0.9 Gm. had been given. In 1927, he reported with Burmeister<sup>5</sup> that he had treated a total of 48 patients by this method, that the drug had been tolerated just as well as the usual arsphenamine and bismuth or mercury injections, and that the results compared favorably with those under the aforementioned treatment. Late observation showed negative Wassermanns and no evidence of syphilis in 68.2 per cent of the cases.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944. Part of a symposium on "Intensive Treatment of Early Syphilis."

was receiving bismuth alone, ten days elapsed between two treatments

We feel, on the basis of the excellent initial results obtained by the Army treatment and the paucity of serious reactions caused by this treatment, that the Army will be encouraged to shorten appreciably its plan of treatment, and make it more intensive by closer spacing of injections and by the giving of more bismuth. From our present knowledge, it appears to us to be the safest, most effective, and most intelligent plan yet devised for ambulatory cases

### City Hospital Plan

Since 1924, the plan of treatment on our service at the City Hospital has been a gradually increasing intensive one. Stimulated by our observations of the results obtained by Professor Kyle, of Vienna, with 800 cases of early syphilis, with a course of eight injections of neoarsphenamine, followed by approximately eight pyrexysms of malaria, we instituted a somewhat analogous plan of treatment for the City Hospital cases of early syphilis (Table 2). Dr. Kyle had claimed cures in a great majority of cases so treated within a year. We used arsphenamine two or three times a week for eight to ten injections, followed by malaria. This plan was continued until about three years ago when, because of lack of hospital space and personnel, we had to discontinue the malaria.

The treatment was devised to meet the requirements of the type of City Hospital patients, which in our case have been mostly prostitutes and of an indigent class.

Most of the women have been prostitutes picked up by the police and found to have early syphilis by the examining physician and sent to the hospital by the court. They have been mostly young women between the ages of 15 and 39, averaging about 22 years, a great majority of them suffer from extensive secondary manifestations of the disease, many with widespread condylomas and ulcerating secondary lesions of every description. On admission each patient had a strongly positive blood Wassermann and all spinal fluids were negative. Many patients fully admitted promiscuous sexual exposures for months with open lesions.

Because of the impossibility of keeping these patients in the institution for more than a few weeks and because of our inability to follow them after discharge from the ward, we felt it imperative, not only for the health of the patient, but also for public health purposes, to give them the greatest amount of antisymphilitic treatment possible in their short hospitalization period.

Based on the results obtained in our experimental work at the Presbyterian Hospital in an

1 cc of 10 per cent suspension of bismuth subacetylate in oil intramuscularly twice weekly for two weeks while in hospital. Sent to clinic for twenty-five weekly 2 cc injections of bismuth after discharge from hospital.

effort to simplify the technic and to shorten the patient's hospitalization, we devised a twelve-day intensive treatment. Our plan consisted of giving large doses of mapharsen and bismuth. All patients received two injections of mapharsen the first day consisting of 120 mg each. The patients of the middle-weight (135-165 pounds) and heavy-weight (165-220 pounds) groups received two mapharsen injections the second day also, and the heavy-weights continued with 120 mg daily for the remainder of the twelve days, whereas the middle-weight and light-weight group had 120 mg daily for the remainder of the first week and 60 mg daily for the second week. The total dosages were 12 Gm for the light-weight group, 132 Gm for the middle-weight group, and 168 Gm for the heavy-weight group. In addition, each patient received 100 mg of bismuth subacetylate intramuscularly twice a week.

At completion of treatment, each patient was referred to the City Hospital Clinic for twenty-five weekly injections of bismuth, the idea being not only to try to prevent infectious relapse, but also to observe the patient. All patients had general physical examinations, dark-field examination, blood Wassermann reaction, blood count, and urinalysis before treatment was begun. Frequently blood Wassermann tests besides clinical observations were made at each visit to the clinic. In all instances, the surface lesions have healed promptly under treatment, and at the time of discharge from the hospital, about two

weeks after admission, all lesions were healed, sometimes before and often within a week.

The injections have been given by the interns or by a nurse. To date we have treated about 71 patients, under the supervision of the resident dermatologist, Dr. Wexler, of whom there were 58 women and 13 men, the approximate distribution into weight groups being light-weight, 57; middle-weight, 13; heavy-weight, 1. Of these 71 patients 40 per cent are continuing treatment with bismuth at the clinic. In none of these has any reaction appeared which did not ultimately clear. Practically every patient is nauseated on the first day of treatment and vomits about four hours after the first injection. The following day most of the patients feel quite well and comfortable and finish their treatment without any discomfort or nausea. We have had four cases of toxic erythema, each clearing in a few days after cessation of treatment. They have been able to resume and complete the treatment without further trouble. There was one case of phlebitis of the injected vein. Ringing in the ears, accompanied by nausea and vomiting, was noted in one patient after the seventh injection.

This state lasted only about four hours, but returned after the eighth injection the following day and persisted for four days. No further treatment was given. The only serious reaction occurred in a patient who had a convulsion and was irrational after the ninth injection. This

was followed by complete recovery in twelve hours. The patient was discharged the following day as normal.

To any physician who has a patient who can be hospitalized we would recommend this form of treatment as a simple one that so far has been unattended by serious accidents and that affords the accepted amount of mapharsen for probable spirochetal sterilization. The added bismuth with its slow absorption would minimize the danger of infectious relapse; and, should the physician be successful enough to continue the bismuth injections for twenty-five weeks longer after hospitalization, it would give him the advantage of frequent observation.

### Clinic Plan

To meet the requirements of the ambulatory patient we have been working on the plan of daily injections of arspenamine for one group, and of mapharsen for another. We tried to have these groups as nearly similar as possible in order to have a more informative comparison of our results.

Approximately a year ago, we began giving daily injections in Vanderbilt Clinic, using arspenamine by syringe method, administering the largest doses at the beginning of the treatment and diminishing to smaller doses toward the end of the course. Because the Clinic is closed Saturdays and Sundays, we have given the injections only five days a week, requiring a month for the completion of the course of twenty injections (Table 3).

We have treated also three cases in our private office, giving seventeen consecutive treatments. These patients were working every day, and none of the three had any reaction of any sort; one of the patients was a ballet dancer and worked every day and every night.

Each of these three patients received approximately 5.2 Gm. of arspenamine each and each was seronegative by the end of three months after termination of the treatment. One

For the next four to five months give one 2 cc bismuth injection weekly

has remained negative as to blood and spinal fluid for approximately a year. The other two have remained clear for six and nine months, respectively.

Of 29 patients treated at Vanderbilt Clinic, ranging in age from 17 to 42, 18 were women. The dosage was gaged according to the weight to the patient, the minimum total dosage was 5 5 Gm for men and 4 95 Gm for women.

The reactions were exceedingly mild, rarely interfering with treatment. Three complained of mild pains in the legs, two complained of a generalized erythema that lasted three days. Treatment was resumed and both completed courses, but one patient had mild nitritoid reactions.

All spinal fluids were negative at beginning of treatment. Two had seronegative primary syphilis, four had seropositive primary syphilis, and the remainder had secondary.

All but seven patients finished their treatments. In this group we have had three relapses and eleven have become completely negative. We have one seropositive primary patient who received only four daily injections, totaling 1 6 Gm.

He failed to appear for observation for eight months. On his return to the Clinic, his blood and spinal fluid were negative by all methods and have remained so for a year.

We are now engaged in studying the effects of daily injections of mapharsen in the treatment of ambulatory patients with early syphilis. All patients are receiving 120 mg daily for ten injections, and to comply with Clinic regulations (no clinic Saturdays and Sundays) we have given the treatment only five days weekly (Table 4). To date we have treated 15 patients, and at least half of these have had nausea and vomiting.

After long and varied experience in the treatment of early syphilis, we are convinced that no

Total	2 34 Gm	40 cc (4 0 Gm)

one plan can be devised that will meet the requirements of each individual case. Practically every one of the various treatment schedules that have been advocated has its own beneficial merit. The five-day plan might be the method of choice for the patient who can be under treatment for only a few days (seafaring men, for example). For still another type of patient who can be hospitalized for a bit longer, a somewhat simpler, less intensive, and perhaps a safer plan can be used, as outlined in that used at the City Hospital at the present time, one including not only mapharsen, but also bismuth. This latter plan of treatment particularly appeals to us, not only because of its simplicity and the comparative freedom from injurious effects, but also because the slow absorption of the bismuth gives hope of decreasing infectious relapses. In addition, this plan allows us to keep the patient under observation for a much longer period.

Again, there is that large group comprising the majority of patients with early syphilis that is treated in office and clinical practice, which must be brought into the scheme of rapid treatment (Table 5). It is for this class of patient that we are especially interested in outlining a plan that will afford quick spirochetal sterilization, and if possible, a lasting cure with the minimum of reactions.

In the cure of syphilis we are convinced that no plan of treatment with arsenic alone so far devised is as effective as a combination of arsenic with heavy metal, or arsenic with fever. Moreover, the added heavy metal or fever is the best insurance that the patient with early syphilis can have against relapse of his infection.

With the above idea in view, we venture to suggest the following scheme.

Our study of intensive arsenotherapy on the ward at Presbyterian Hospital convinced us of the advantage of beginning with large doses of the arsenical and gradually diminishing the dose toward the end of the course, this form of treatment proving much more effective than beginning with small doses. It is true that this large initial dose on the first day of treatment will increase appreciably the reactions on that day, but such reactions are usually not of a serious nature in a patient with early syphilis and the patient is usually symptom-free the following day.

There is no question in our minds that the more intensive the treatment during the first few days without any serious effects on the patient, the greater are our chances of effecting a cure.

Also, our experience teaches us the necessity of giving a heavy metal both in conjunction with the arsphenamine and after completion of the arsenical treatment. This more slowly absorbed and retained drug not only increases our chances of getting a satisfactory result and practically obviating mucocutaneous relapses, but, by continuing the treatment of bismuth for a number of weeks after the completion of the arsenical, we are enabled to keep the patient under observation.

Should the patient disappear from treatment after even the first course of the arsenical, we still believe he has quick spirochetal sterilization and a better than 50 per cent chance of being cured.

Obviously, this strenuous form of treatment cannot be given to all patients because of physical infirmities, age, occupation, social reasons, or because of intolerance. In these cases we would advocate a less intensive program of therapy (Table 6).

You will notice that this plan of treatment gives almost as much mapharsen (2.34 Gm.) as, and more bismuth subsalicylate (4.0 Gm.) in twenty weeks than the Army plan of treatment of 2.4 Gm. of mapharsen and 3.2 Gm. of bismuth subsalicylate in twenty-six weeks, a saving of six weeks. However, we advocate a continuation of the bismuth at weekly intervals for twelve to fifteen weeks longer.

Should your patient not be able to fit into any of the above plans, you still have the excellent treatment schedule of the Army that you may use (Table 1). This standard Army plan, as you probably know, covers a period of twenty-six weeks, and consists of a total of forty injections of 60 mg. doses of mapharsen and sixteen injections of 0.2 Gm. of bismuth subsalicylate. Mapharsen is given twice a week for the first

ten weeks. One injection of 0.2 Gm. of bismuth subsalicylate is given weekly for the first five weeks. After ten weeks of mapharsen, the patient is given five weekly injections of bismuth, 0.2 Gm. each. He is then given mapharsen twice a week for the next ten weeks, and during the last six weeks of mapharsen, he is given weekly injections of bismuth subsalicylate.

In all cases we make a thorough physical and neurologic examination, darkfield examination, a blood Wassermann, and one or more blood precipitation tests and a spinal fluid examination. We recommend that a blood Wassermann should be taken at least once a month while the patient is receiving treatment, and every two or three months afterwards during the first year and every four to six months afterwards. We repeat the spinal fluid test at the end of one year from the time of his first starting treatment.

It is obvious that no definite statement can be made at this time on the ultimate outcome of any intensively treated cases, because of the short duration of observation. Perhaps many years should elapse before one can make a final appraisal of any intensive arsenotherapy.

## Summary

A short review of intensive treatment of early syphilis with the arsenicals by previous investigators is here outlined.

The twelve-day mapharsen-bismuth treatment plan as employed at City Hospital is described.

A daily plan of arsphenamine or mapharsen treatment as used at the Vanderbilt Clinic is presented.

Two plans, one intensive and the other semi-intensive, are especially devised for use by the general practitioner in the treatment of primary and secondary syphilis in office practice.

# INTENSIVE TREATMENT OF EARLY SYPHILIS—METHOD OF EAGLE AND HOGAN

GEORGE MILLER MacKEE, M D , and GIRSCH D ASTRACHAN, M D , New York City

**T**HE Eagle and Hogan method of treating syphilis consists of triweekly injections of mapharsen, given for a total of six, eight, or ten weeks (dosage approximately 1 mg per kilogram of body weight). Bismuth may be given concurrently once a week. This method was introduced by Eagle and Hogan after a large-scale experimental study on rabbits<sup>1,2,3</sup>. In July, 1942, they had already accumulated data on approximately 500 treated patients<sup>4</sup>. On the basis of their experimental data and clinical study, they came to the conclusion that the above-mentioned method "is a safe procedure and that it will apparently give therapeutic results comparable to those obtained by average clinic practice."

We began to use this method in September, 1942, at the suggestion of Dr. Eagle<sup>4</sup>. To date 61 patients have been treated, of whom 4 were women and 57 men. The maximum age was 49, the minimum 16. Twenty-two patients were in the age group from 16 to 20 years, 27 were from 21 to 30 years, 10 were from 31 to 40 years, and 2 patients were 46 and 49, respectively.

There were 9 patients with seronegative primary syphilis, 33 with seropositive primary, 18 with secondary syphilis, and one with latent syphilis. There were 54 cases from the Metropolitan Hospital and Dispensary (service of Dr. Van Alstyne Cornell), 7 from the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital (service of Dr. Fred Wise). A large majority of the patients (54) were hospitalized, for the entire period of the treatment or for part of it, in the Metropolitan Hospital. Mapharsen was given three times weekly. In order to avoid a Herxheimer reaction, we began treatment, with the exception of cases of seronegative primary syphilis, with a bismuth injection, followed by an arsenical, the arsenical being started with one half of the maximum dosage suitable for each particular case.

The total number of mapharsen injections given to 61 patients was 1,069. Twenty-six patients discontinued treatment after they had received on the average only 10.4 injections of mapharsen. Thirty-five patients completed the course of treatment and received on the average 23.9 injections of mapharsen. The majority of these patients were under treatment for only eight weeks. In a few cases, however, because of some mild reactions, the treatment schedule and dosages were somewhat modified and the treatment continued for a few weeks longer.

Bismuth was given concurrently once a week. Icterus indices, serologic tests, and urine examinations were done once a week. Complete blood counts were done only in cases of complications.

The majority of the patients who completed the treatments underwent a lumbar or cisternal puncture before they were discharged. A follow-up letter was given to the patient leaving the hospital, and he was advised to show the letter to any physician he consulted or any medical officer. In this letter the kind of treatment the patient had received was described, and cooperation in the evaluation of this method of treatment was requested. It was suggested that examination and blood tests be repeated at one-month intervals for six months following treatment, and at two-month intervals for the next six months, and three-month intervals for the second year.

The letter also contained a request that no further specific treatment should be given, unless there was clear-cut evidence of clinical relapse, or the strength of the quantitative blood test increased significantly.

Those patients who requested a discharge before the intensive method was completed were referred to the Board of Health or some other clinic for further routine antisyphilitic therapy.

## Effect of Intensive Therapy on Visible Lesions

The average amount of mapharsen required for the disappearance of primary lesions was 254 mg. The average time required was 12.6 days. The average number of injections given was five of mapharsen and two and a half of bismuth. The average amount of mapharsen required for the disappearance of secondary lesions was 394 mg. The average time required was

17.6 days. The average number of injections given was 7.4 of mapharsen and 3.2 of bismuth.

*Case 1.*—In one patient with secondary syphilis, D. B., the lesion healed first after five injections of mapharsen (total amount 220 mg.), and two injections of bismuth were given within fifteen days. Two days later, while the patient was still under treatment, two small, pea-sized, well-defined, eroded papular lesions appeared on each side of the meatus. The darkfield examination revealed the presence of *Spirochaeta pallida*. These lesions healed only after eight injections of mapharsen and three of bismuth were given. Altogether, in order to clear up the secondary eruption and the cutaneous relapse it required fourteen injections of mapharsen (total amount, 715 mg.) and five injections of bismuth. The time required was thirty-seven days. We also had the opportunity of observing a case of arseno-resistant syphilis.

*Case 2.*—O. S., 21, a colored man, was admitted to the Metropolitan Hospital in May, 1943, with the history of an eruption of three weeks' duration. The eruption was most pronounced on the trunk, upper and lower extremities, and around the anus. It was composed of papular and papulosquamous lesions and was accompanied by a generalized adenopathy. Spirochetes were found in the serum of one of the lesions. Intensive therapy was instituted. In spite of twenty-six injections of mapharsen and nine of bismuth many lesions failed to heal. Edema of the prepuce and of the glans also persisted. Biopsy from one of the lesions confirmed the diagnosis of syphilis. The Wassermann and Kahn tests

showed partial reversal; the Wassermann was 2 plus and Kahn 2 plus one week after mapharsen was discontinued. A case of an infectious relapse, which developed during the second month of arsenotherapy, was reported recently by Schoch and Alexander.<sup>5</sup>

### Effect of Intensive Therapy on the Serologic Reactions

Thirty-five patients completed the course of treatment and received on the average 23.9 injections of mapharsen and 9.1 injections of bismuth salicylate. Among these 35 there were 18 whom we were able to follow up for a certain length of time, following the completion of the intensive method of therapy. The period of post-treatment observation ranged from three weeks to fourteen months. In spite of every effort made the other 17 patients could not be followed up. Among these 35 patients were 7 with seronegative primary syphilis, 16 with seropositive primary syphilis, 11 with secondary, and 1 with latent syphilis (see Tables 1 and 2).

In 20 of 34, or in 58.8 per cent of early syphilitic cases the serologic reactions reversed to negative (in seronegative cases the serologic reactions remained negative). See Table 3. In 2 other cases the serologic reactions reversed to negative; however, the results should be accepted with reservation (cases P. B. and S. J.).

*Case 3.*—P. B., a man with seropositive primary

TABLE 2.—ILLUSTRATING THE EFFECT OF INTENSIVE TREATMENT ON THE SEROLOGIC REACTIONS OF PATIENTS WHO WERE UNDER OBSERVATION AFTER TREATMENT WAS COMPLETED

TABLE 3.—EFFECT OF INTENSIVE TREATMENT ON THE BLOOD SEROLOGIC REACTION OF PATIENTS WITH EARLY SYPHILIS (ANALYSIS OF TABLES 1 AND 2)

Total number of patients who completed treatment	34
Number of patients whose serologic reaction reversed to negative (or seronegative cases which stayed negative)	20 (58.8%)
Number of patients whose serologic reaction reversed to negative (results accepted with reservations)	2 (5.8%)
Number of patients whose serologic reaction reversed partially (average follow-up time 6.4 weeks)	6 (17.6%)
Number of patients whose serologic reaction remained unchanged on or about the time when treatment was completed (no further follow-up was done)	4 (11.7%)
Number of patients who presented therapeutic failures	2 (5.8%)

TABLE 4.—INFLUENCE OF THE SPACE OF THE STIMULATING INJECTION ON THE AVERAGE SEROLOGIC REACTION TO REVERSE A POSITIVE SEROLOGIC REACTION TO NEGATIVE (ANALYSIS OF TABLES 1 AND 2)

All Stages of Syphilis	Sero-negative	Sero-positive
Primary	21	13
Secondary	7	5
Average number of mapharsen injections given before the serologic reaction reversed to negative	21.3	22.3
Average amount of mapharsen given before the serologic reaction reversed to negative	1,100 mg.	785 mg.
Average amount of mapharsen given before the serologic reaction reversed to negative	1,100 mg.	1,166 mg.
Average amount of mapharsen given before the serologic reaction reversed to negative	1,100 mg.	1,480 mg.

syphilis, received twenty-four injections of mapharsen (total amount 1,180 mg.). At about the time when the treatment was completed, his blood serology was 4 plus. He was discharged from the hospital but he did not report for further checkup. Through the efforts of the Social Service he was located seven months later. The blood serology was checked and was found to be negative. We found out, however, that since his discharge from the hospital, he had received 1 cc. of bismuth salicylate and 0.45 cc. of neoarsphenamine given to him in some clinic about two weeks before the negative serologic reaction was obtained. We don't think that this amount of treatment could greatly influence the results of the serologic test. And we accept the case, with some reservations, as one in which the results of the intensive therapy were probably good.

*Case 4.*—The blood serologic reaction of S. J., a man, reversed to negative on March 29, 1943, after nineteen injections of mapharsen were given, and has remained negative (one-year observation). The first spinal fluid examination was done two months after the discontinuation of therapy and gave an irregular reaction. The Wassermann with cholesterinized antigen was plus-minus in 0.4 cc. of fluid.

The colloidal gold curve was 4455543100. Eight and one half months later, on April 17, 1944, another spinal-fluid examination was done, and the spinal fluid was found to be completely negative. From the date of the first spinal-fluid examination to the time of the second one, the patient received on various dates a total of 6 cc. of 10 per cent bismuth salicylate in oil suspension, and 1.0 of neoarsphenamine.

This amount of therapy could hardly change a positive spinal fluid into a negative one. We think, therefore, that the laboratory findings of the first spinal-fluid examination were probably caused by some technical error. And we believe, with some reservation, that the results of the intensive therapy in this case were probably good.

In 6 out of 34, or 17.6 per cent of the cases, the serologic reactions reversed partially (average follow-up time was 6.2 weeks). In 4 out of 34, or in 11.7 per cent, the serologic reactions remained unchanged on or about the time when treatment was completed (no further follow-up was done).

Two cases out of 34, or 5.8 per cent, may be considered as therapeutic failures. One was the case of S. O., the patient with arseno-resistant syphilis (see above). The other was that of secondary syphilis in which the serologic reaction of the blood became completely negative two and a half months after completion of the intensive therapy (twenty-four injections of mapharsen, total amount 1,105 mg., and eight injections of bismuth). The spinal fluid was normal except for a plus-minus Wassermann reaction to 1 cc. of the fluid. A spinal puncture was repeated three weeks later. The spinal fluid was found to be

normal again except for a 1 plus Wassermann reaction to 0.2–0.8 cc. of fluid.

Taking into consideration that in the cases in which the serologic reactions reversed partially this improvement was present after an average of only 6.2 weeks of post-treatment observation, we are justified in believing that these 6 patients will probably show further improvement in their serologies within the next few months. We are justified in adding these 6 cases to the 20 in which the serologic reactions reversed to negative, and we may say that in 26 out of 34 cases of early syphilis, or 76.4 per cent, the results of intensive treatment were good. (We did not include in this group the two patients, S. J. and P. B., in whom the results obtained were accepted with reservation). Among the patients who completed the treatment there were 4 in whom the blood serologic reactions reversed to negative, and remained negative throughout the time of observation (seven to fourteen months) (see Table 2). The spinal fluid was found to be normal immediately following the termination of treatment. In one case, the spinal fluid was re-examined fourteen months later and found to be normal. One patient developed a probable case of reinfection.

*Case 5.*—B. J., 29, male, completed the intensive therapy on May 16, 1943, and since then the Wassermann and Kahn tests of the blood taken about once a month were found to be negative and remained negative until and including December 30, 1943. The spinal fluid was found to be normal. On January 24, 1944, he appeared in the office of one of the authors (G. A.) presenting two lesions on the penis of five or six days' duration. He stated that for the last few weeks he had had intercourse with five different women. The last intercourse was about January 10 or 12, about ten days before the lesions appeared. The lesions were pea- to dime-sized, well defined, indurated, and were located about one inch from the region of the original chancre. There was a moderate bilateral, indolent inguinal adenopathy. A darkfield examination of the serum from the lesions showed the presence of *S. pallida*. Serologic tests were taken every other day. The results were as follows:

January 25:	Wassermann—negative..	Kahn—2 plus
January 27:	Wassermann—B.H.P....	minus, plus-minus
	B.H.C....	1 plus, 2 plus
	Kahn.....	2 plus
	Kline diagnostic.....	1 plus
	Kline exclusion.....	3 plus
January 29:	Wassermann—negative..	Kahn—negative
February 1:	Wassermann—B.H.P....	plus-minus 1 plus
	B.H.C....	3 plus 4 plus
	Kahn.....	plus-minus
February 3:	Wassermann—B.H.P....	4 plus 4 plus
	B.H.C....	4 plus 4 plus
	Kahn.....	1 plus
February 5:	Wassermann—B.H.P....	4 plus 4 plus
	B.H.C....	4 plus 4 plus
	Kahn.....	4 plus

The results of the tests done on January 29, 1944, most probably were due to some mistake

TABLE 5.—INFLUENCE OF THE STAGE OF THE SYPHILITIC INFECTION ON THE TIME REQUIRED FOR THE REVERSAL OF A POSITIVE SEROLOGIC REACTION TO NEGATIVE

	All stages	Sero-negative	Sero-positive	Secondary
Total number of patients whose serologic reactions reversed to negative	17	3	7	7
Number of patients whose serologic reactions reversed to negative before treatment was completed	3	3 (100%)	4 (57.1%)	2 (28.6%)
Number of patients whose serologic reactions reversed to negative after treatment was completed	8	0	3 (42.9%)	5 (71.4%)
Average post-treatment time required for reversal of positive serologic reactions to negative	0		1 5 weeks	7 4 weeks

in the laboratory. After the diagnosis was established the patient received the following treatment:

January 27 Bismuth—1 cc  
 January 29 Mapharsen—30 m m  
 January 30  
 February 1  
 February 3  
 February 5

The patient was inducted into the army on February 8, 1944.

Table 4 illustrates the influence of the stage of the syphilitic infection on the amount of treatment necessary to reverse a positive serologic reaction to negative. While the average number of mapharsen injections given before the serologic reactions reversed to negative was 21.3 for all forms of early syphilis, it was 13.7 for seronegative primary syphilis, 20.5 for seropositive primary, and 25.3 for secondary syphilis.

As to the average of the total amount of mapharsen given before the serologic reaction reversed to negative, it was 1,190 mg of mapharsen for all forms of early syphilis, only 785 mg for seronegative primary, somewhat more—1,166 mg—for seropositive primary and the largest amount (1,480 mg) was for cases of secondary syphilis.

The stage of the syphilitic infection also had an influence on the time required for the reversal of the positive serologic reaction to negative (see Table 5). In 9 cases the serologic reaction reversed to negative before the treatment was completed. Among these there were 3 seronegative cases, or 100 per cent of the seronegative group, 1 seropositive case, or 57.1 per cent of the seropositive group, and only 2 secondary cases, or 28.5 per cent of the secondary group,

SHIP BETWEEN ARSEN GIVEN PER KG IN THE SERO AND SECONDARY

	Average Amount of Mapharsen (in Mg.) Given per Kg of Weight	Total Amount of Mapharsen Given (in Mg.)
Patients whose serologic reactions reversed to negative	22.3	1,481
Patients whose serologic reactions reversed partially	20.2	1,238
Patients whose serologic reactions remained unchanged on or about the time when treatment was completed	20.3	1,230
Patients who presented therapeutic failures	22.0	1,432

in which the serologic reactions reversed to negative. The effect of the therapy on the serologic reactions was influenced to a certain degree by the total amount of mapharsen given per kg of weight (see Table 6). Patients whose serologic reactions reversed to negative received on the average a total amount of 22.3 mg of mapharsen per kilo of weight (total amount 1,481 mg).

Those patients whose serologic reactions reversed partially received on the average 20.2 mg per kg of weight (total amount 1,238 mg). Those whose serologic reactions remained unchanged on or about the time when treatment was completed received on the average 20.3 mg per kg of weight (total amount 1,230 mg).

Among those cases in which the serologic reactions reversed to negative only after the treatment was completed, the seropositive group required an average of 1.5 weeks only, while the secondary cases required an average of 7.4 weeks.

We treated only one case of latent syphilis. This patient received twenty-eight injections of mapharsen (total amount 1,715 mg) and thirteen injections of bismuth. The serologic reaction did not show any improvement after five months of post-treatment observation.

### Untoward Reactions

Among the 61 patients who received 1,069 injections, there were 34 who complained of or presented eighty-one reactions. Among these reactions fifty were of a mild evanescent character, such as nausea and vomiting or headache on the day of the treatment, or fever up to 101 F, which lasted for a few hours. Some of the patients in this group complained of occasional weakness or dizziness, pain in the abdomen, or diarrhea. All these mild reactions usually did not recur when the dosage of mapharsen was

TABLE 7.—COMPARISON OF THE PERCENTAGES OF OUR PATIENTS EXHIBITING TREATMENT REACTIONS WITH THE PERCENTAGES OF PATIENTS TREATED BY THE INTRAVENOUS DRIP METHOD\*

Our Figures		Elliott's First Series	Figures Second Series
Reactive cases	55.7	91.2	95.5
Fever	11.4 Secondary fever	24.0	56.9

fatal	0	0.2	0.4

\* Figures taken from articles by Elliott, *et al.*: J.A.M.A. 117: 1161 (Oct. 4) 1941.

diminished. Eight patients developed Herxheimer reactions. Six of these had an elevated temperature (100–103 F.) on the day of the injection. One showed a marked swelling of the prepuce, one complained of pain in the stomach radiating to the back, one had a Herxheimer reaction in the form of a pruritus lasting for one day after the first injection.\*\*

There were 18 patients who presented twenty-three delayed reactions. Six developed some eruption or pruritus. These were of a minor character and did not delay further treatment in any noticeable way. Two patients developed eruptions which most likely were not caused by the mapharsen therapy, but were only coincidental to it. In one case it was folliculitis, in the other one it was a pustular eruption. In another case a papulopustular dermatitis reappeared even after the dosage of mapharsen was decreased. It was considered important enough to warrant discontinuation of the intensive method. One patient developed a probable trigeminal neuralgia lasting for about two weeks, one developed neuritis lasting for a few days only, two had recurrent attacks of fever, and one a severe form of an ulcerative stomatitis.

Two patients presented disturbances in the hemopoietic system (mild leukopenia in one case, and increase in the percentage of band forms of polynuclears in the other). Reactions were serious enough to warrant the discontinuation of the intensive therapy in 7 cases. Two of these cases (one jaundice and nephritis, the other encephalopathy) are noteworthy.

Case 6.—M. W., 21, male, colored, was admitted to the Metropolitan Hospital on August 19, 1943, with the diagnosis of primary syphilis. Follow-

ing the fourth injection of mapharsen (total amount of mapharsen given was 210 mg.), the patient developed chills and fever up to 105 F. for three days. The patient complained of aches and pains over the entire body, and some nuchal rigidity was present. A complete blood count was normal except for the leukocytosis (21,500). The spinal fluid was found to be normal. The urine, on August 31, 1943, showed the presence of granular casts which lasted for five weeks. The patient began to show some yellowish discoloration of the conjunctivae, though the icterus index was only 9. It did rise, however, gradually and reached 100 at one time.

He was transferred to the medical department,† where he was treated with daily infusions of 1,000 cc. of 5 per cent glucose solution for one week. After that high carbohydrate and high protein diet was instituted. For some time he received 50 Gm. of sugar twice a day as a supplement to his diet. He continued to improve. On December 2, 1943, about three months after the onset of the jaundice, the icterus index was 10.2. Besides the above-mentioned medications, he received, during almost the entire time, crude liver extract injections, 1–4 cc., three times weekly, and small doses of bismuth sodium tartrate or bismuth salicylate. He was discharged from the hospital and referred to the clinic on December 16, 1943. On this day, three and one-half months after the onset of the jaundice, the icterus index was found to be normal (6.5). It is interesting to note that a 4-plus serologic reaction changed to negative following four injections of mapharsen (total amount 210 mg.) and two of bismuth salicylate (4 cc.) and six of bismuth sodium tartrate.

Case 7.—W. L., 25, male, colored, developed a severe headache on February 9, 1943, one day after the sixth injection of 60 mg. of mapharsen (total amount of mapharsen given was 330 mg.). The next day (February 10, 1943) he vomited and complained of feeling very ill; his temperature was 100 F. by mouth; there was some nuchal rigidity, but the Kernig sign was negative. On February 11, 1943, the patient stated that he had had frequent headaches for the last four or five years, but the headache for the last few days was exceptionally severe (frontal and occipital). On February 12, 1943, a lumbar puncture was performed and 20–25 cc. of fluid was removed. The fluid spurted under increased pressure. According to the patient the headache disappeared almost completely, five minutes after the puncture. The cell count was 225 (mostly monocytes); the globulin was not increased; the Wassermann test was negative; and the colloidal gold curve was normal. The patient felt very good after the lumbar puncture; he remained in the hospital for two more weeks, during which time he felt perfectly normal and received bismuth therapy. It is noteworthy that in this case, following six injections of mapharsen (total amount given was 330 mg.) and five injections of bismuth a 4-plus serologic reaction reversed to negative.

\*\* Recently a "fever conjunctival injection-facial edema syndrome" following the intensive therapy was described by Cole.<sup>4</sup>

† Permission to publish these data was given by Dr. Linn J. Boyd, director, Department of Medicine, Metropolitan Hospital.

One patient presented an icterus index of 16.0. With the exception of two cases of nephritis, there were no cases of real renal damage. One patient complained of frequent urination and some pain in the kidney region. Urine examination revealed nothing abnormal except a faint trace of albumen. Five patients had faint traces of albumen in the urine, lasting for few days only, which cleared up while the patient was under treatment with mapharsen.

It is noteworthy that four of our patients were being treated during ten days for concomitant gonorrhea with sulfathiazole. In one of these cases mapharsen was instituted only after sulfathiazole was discontinued. This patient did not show any complications. The other three, however, received mapharsen injections once or twice weekly while receiving 3-4 Gm daily (during ten days). These 3 patients had, during this time, one or several attacks of fever of 100-104 F.

*Case 8*—One of our patients, S. J., developed at different times several reactions, such as severe Herxheimer, severe pain in the abdomen for twenty-four hours, pains in the arms and legs lasting for a few days, changes in the blood count (polymorphonuclears 41 per cent, band forms 12 per cent), severe trigeminal neuralgia lasting for about two weeks. However, by delaying the injections of mapharsen for several days or by decreasing the dosage we managed to avoid more serious complications and we were successful in completing the necessary therapy. It lasted, however, three months and five days.

Table 7 shows the comparison of percentages of our patients exhibiting treatment reactions with the percentages of patients who were treated by the intravenous drip method.

It can be seen that, with the exception of toxicodermas, renal complaints, and nonfatal encephalopathies, the percentage of total patients who exhibited specific treatment reactions was much lower in our group than among the patients who were treated by the drip method. As to the toxicodermas, the percentages were about the same in both groups. We have to consider the fact, however, that in two of our patients it was unlikely that the eruptions (folliculitis, pustular eruption) were caused by mapharsen therapy, and that would lower the percentage of toxicodermas in our group to 6.6. Besides that, the toxicodermas among our patients were mostly of the nonserious type. There was not a single case of exfoliative dermatitis. As to the greater percentage of nonfatal encephalopathies in our group, 1.6 versus 0.4-0.6 in Elliott's figures, this difference was well compensated for by the complete absence of fatal encephalopathies in our group whereas in Elliott's group the percentage

of patients who developed fatal encephalopathies ranged from 0.2 to 0.4.

### Comment

With the exception of the arseno-resistant case, and the case in which cutaneous recurrences appeared while the patient was under treatment, visible lesions responded properly to the intensive therapy. Primary and secondary lesions healed in an average of 12.6 and 17.6 days, respectively, following an average of 5.0 and 7.4 mapharsen injections, respectively.

As for the effect of this therapy on the serologic reaction, in 58.8 per cent of the cases the serologic reactions reversed completely to negative, while in the other 17.6 per cent the serologic reactions reversed partially. And if we add these percentages, we may say that in about 76.4 per cent the results of the treatment were good. Among these cases were 4 in which the serologic reaction reversed to negative and remained negative throughout the time of observation (seven to fourteen months). One of these cases developed a probable reinfection.

The average number of mapharsen injections and the average total amount of mapharsen necessary to reverse a positive serologic reaction to negative increased in direct proportion to the increase of the duration of the syphilitic infection. The stage of the infection also had an influence on the time required for the reversal of the serologic reaction to negative. In 100 per cent of the seronegative group, in 57.1 per cent of the seropositive group, and in only 28.5 per cent of the secondary cases the serologic reactions reversed to negative before treatment was completed.

The total amount of mapharsen given per kilo of weight influenced, to some degree, the results of therapy. In cases of seropositive primary and secondary syphilis in which the serologic reactions reversed to negative the patients received on the average 22.3 mg of mapharsen per Kg of weight (average total of mapharsen received was 1,481 mg).

There were only two therapeutic failures in our group (5.8 per cent). Taking all the above-mentioned factors into consideration, it appears to us that the method of Eagle and Hogan is quite efficacious.

In two cases in which serious reactions occurred (jaundice, encephalopathy), the serologic reaction reversed to negative after only four and six injections of mapharsen, respectively, and eight and five injections of bismuth, respectively, were given.

The untoward reactions observed among our cases were in most of them of a mild character. The treatment had to be discontinued because of the severity of reactions in only 7 cases. We

stress the fact that only two serious reactions were observed (jaundice, encephalopathy) and that no cases of exfoliative dermatitis were seen, and most important of all, there were no fatalities. We feel that the method of Eagle and Hogan is a comparatively safe procedure, in comparison with other intensive methods, especially the intravenous drip method.<sup>7,8</sup>

Because the method of Eagle and Hogan may, and does, cause more untoward reactions than the old routine procedure of antisyphilitic therapy, it is suggested that it should be used with caution, preferably under the supervision of a trained syphilologist. Hospitalization is not absolutely necessary, although it is very advantageous.

The lack of cooperation on the part of some patients as far as completion of the minimum amount of treatment and follow-up are concerned, presents a difficult problem. And it is therefore suggested that this method should be employed preferably in cases of intelligent, cooperative, and careful patients. These patients should be told, however, of the experimental character of this procedure, and of the

possibility, although rare, of grave complications.

## Conclusions

1. The method of Eagle and Hogan appears to be an efficacious method of antisyphilitic therapy.

2. It causes fewer reactions than the intravenous drip method.

3. It is still in the experimental stage, and it should be used cautiously, preferably under the supervision of a trained syphilologist.

4. This method may be employed when dealing with cooperative and careful patients.

## SEROLOGIC ASPECTS OF EARLY SYPHILIS

R. C. ARNOLD, M.D., and MARGARET R. ZWALLY, M.A., Staten Island, New York

THE laboratory phase in the serum diagnosis of syphilis is portrayed by the results of the serodiagnostic tests. The serologic manifestation varies with the stage and duration of the syphilitic infection and the normal defensive forces of each individual, and is modified by the treatment procedures.

The type and number of serologic tests which may be selected for laboratory studies will vary with specific clinical programs. The detailed serologic examinations by a battery of tests, frequently used in special diagnostic problems or in research and experimental therapeutic investigations, may not be a practical serologic routine for conventional case-finding, diagnostic, and therapeutic studies. The public health laboratory and routine clinical laboratory cannot be expected to furnish such extensive service. In a few instances the routine may be elaborated to include comprehensive serologic testing, but this can be effected only by a longer or shorter period of transition.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944. Part of a symposium on "Intensive Treatment of Syphilis."

From the Venereal Disease Research Laboratory, U.S. Marine Hospital, Staten Island, New York.

Before establishing a new serologic routine within a laboratory due consideration should be given the adequacy of the physical space and equipment, the skill and experience of the technical personnel, and the average daily specimen load. A daily load of several thousand or even several hundred blood and spinal fluid specimens can be handled properly only in those laboratories which have well-organized serologic routines especially integrated for their respective activities. At all times the tests should be performed according to the latest modifications of accepted techniques utilizing standardized antigens and test reagents together with adequate intra- and inter-laboratory control measures. The results of a single serodiagnostic test properly conducted are more valuable than the results of any given number of tests performed with random unauthorized modifications designed to ease the serologic burden.

The seronegative picture of the invasive period of syphilis is followed by a transition through the doubtful to the positive pattern which develops soon after the clinical appearance of the chancre. The serologic titer, gaged by quantitative tests, continues to rise to a peak for each patient. The highest titers are observed in the secondary stage

of syphilis. The favorable serologic response to treatment in early syphilis proceeds gradually to the negative state. The reactivity pattern is not pathognomonic of syphilis, as similar patterns may be observed in other diseases, such as leprosy, malaria, virus pneumonia, infectious mononucleosis, vaccinia, and the common febrile disorders. The diagnosis of syphilis should not be made without carefully evaluating the anamnestic record, the clinical findings, and the combined laboratory data.

In a limited number of patients treated for darkfield-positive primary syphilis, the blood serum will maintain a consistently negative serologic pattern with all tests. Usually, when the primary lesion has been present less than a week the reagin content is below the detectable threshold of the serodiagnostic tests. In untreated primary syphilis, if blood specimens are obtained at frequent intervals, the number of doubtful and positive reports will increase and thereby formulate a definite serologic pattern for each individual serum. At the same time, the quantitative tests show evidence of increasing titer until a peak is reached (see Chart 1).

As a rule the more sensitive tests will be the first to give doubtful and positive reactions and

the last to show reversal to seronegativity. However, variations in the serologic pattern will be noticed in which a less sensitive test may give the first positive findings. If the serologic status is determined by a single test the report may be positive, doubtful, or negative according to the test employed. If two or more tests are used, the report may contain any combination of results but the entire picture will reveal the true serologic status. By specimen selection it is possible to demonstrate various reactivity patterns in the diagnostic and in the treatment phase (see Charts 2 and 3).

Rare and unusual serologic reactivity patterns are sometimes observed in darkfield-positive primary syphilis. Repeated examinations established test patterns of single positive reactions in a battery of six tests. This atypical pattern followed the usual course of seroreversal in the post-treatment observation period (see Chart 4).

It is realized that technical or other errors may cause atypical or changing patterns, but these can be easily identified when compared with the consistent individual reactivity pattern.

Even though the pretreatment serologic reports are negative, the majority of patients with darkfield-positive primary syphilis can sooner or later be classified as seropositive because the positive

pattern develops during treatment. The development of the early reactivity pattern frequently appears to be accelerated by the institution of antisyphilitic treatment. The process may develop so rapidly that the true pattern may be masked, as several tests often become positive on the same day (see Chart 5).

The diagnostic tests have been used as indicators of the serologic response to various treatment schedules. The most satisfactory picture is the completely negative reactivity pattern observed in the syphilitic patient who is placed on appropriate treatment soon after the original lesion is discovered (see Chart 6).

Nearly all patients with primary or secondary syphilis will be in the seropositive phase for varying time intervals before therapy can be instituted. In early seropositive primary syphilis there may be a lag in the development of other demonstrable clinical lesions although there is an increase of the serologic titer which usually reaches the highest peak in secondary syphilis. Under successful therapy the rapidity of seroreversal appears to have some relationship to the duration of syphilis and the serologic titer.

It is noted in Chart 5 that the serologic response to treatment was rapid in the patients whose pretreatment reports were negative or doubtful. Patients with secondary syphilis may be expected to remain in the post-treatment

NOTE Quantitation carried out in whole serum serum diluted 1 1 with saline serum diluted 1 2 with saline etc

positive phase two to four months longer than patients with primary syphilis. The serologic reactivity pattern of an occasional patient, however, may remain consistently positive throughout the first year of post-treatment observation (see Chart 7).

The failure to obtain a satisfactory serologic response to treatment is very distressing to the patient and presents a serious problem in therapeutic evaluation for the syphilologist.

The post-treatment serologic response does not always proceed to and remain in the seronegative phase. Serologic relapses give fairly typical reactivity patterns, such as is noted in Chart 8. The serologic response was favorable throughout the eighty-one days of post-treatment observation. A definite increase in positive findings was noted on the one hundred and tenth day, after which the patient was retreated. Following the second series of treatments the serologic response continued toward the negative zone, which was reached at the end of the first year.

Additional serologic data may be obtained by supplementing the qualitative tests with quantitative methods. The quantitative tests portray graphically the gradual reduction of reagin titer from the peak to the lower range of the qualitative tests which then record the last evidence of

positive findings. The quantitative tests are especially valuable in gauging serologic response, as they indicate the decreasing titer or the development of a serologic relapse, while at the same time the qualitative tests give only an unvarying positive report (see Chart 9).

### Summary

The reports obtained from a battery or series of different tests furnish essential data which can be correlated with the clinical status and therapeutic response. The number and type of serologic procedures will vary according to the need for a comprehensive report. The reports from a battery of four, or seven, or ten serodiagnostic and quantitative tests yield proportionately more complete serologic patterns which are helpful in the evaluation of new therapeutic measures and the conduct of other research investigations. A limited serologic routine will furnish sufficient data for the usual diagnostic purposes and for the evaluation of clinical response to an established treatment. If limited serodiagnostic services are used, it must be realized that certain syphilitic serums will escape detection and that the serologic reports may not be in complete agreement with the reports from another laboratory using different test procedures.

### Discussion of Symposium

Dr. Frank C. Combes, New York City—A symposium based on the intensive therapy of syphilis by methods applicable to ambulatory patients is particularly timely and the essayists have made valuable contributions to our knowledge of the treatment of this disease. The average busy physician, however, who is not in close touch with the development of intensive arsenotherapy, must be somewhat confused by the many and varied systems recommended by different investigators, but he must remember that all these methods are still in the experimental stage and must stand the test of time. Changes are still being made in interval and dosage,

and so rapidly, I dare say, that by the time these papers are published the schedules recommended will have been superseded by others, or by penicillin.

Thirty-two years ago Paul Ehrlich remarked that "as in the pursuit of fishing, anyone who wishes to catch the fish in a wide river will only succeed in obtaining a satisfactory result if net is attached to net and the last part of exit is barred, so for an experimenter in a wide field, the success depends on the harmonious working together of many."

In the various schedules used for intensive treatment of early syphilis, it is possible to standardize our methods, since most of the patients are young

and in robust health, their immunologic statuses are essentially identical, and the infections of each are in a relatively similar stage.

In any system of treatment it is essential that we attain a favorable balance between the parasitotropic action of the remedy and its organotropic action. As regards mapharsen, independent of the frequency of injection or duration of treatment, the vast majority of patients have been "cured" by 20-30 mg. per Kg., or approximately 1,500-2,000 mg. in a man weighing 60 Kg. It is necessary, primarily, to determine the margin of safety provided by any intensive procedure on a basis of over what period of time and in what individual dosage the remedy should be given. These depend upon toxicity of the drug as determined by the ability of the patient to absorb, detoxify, and excrete it.

Experience has shown that this margin of safety bears an inverse relationship to the time over which the drug is administered. The mortality in the usual weekly injection procedure, extending over a period of several months, is approximately 1 in 3,000. The administration of 1,200 mg. in a "five-day intravenous drip" has a mortality rate of one in 200. There are no reliable data for the one-day routine, but the arsenicals are far too toxic for administration of a curative dose in one twenty-four-hour period even when combined with hyperpyrexia.

The triweekly injection routine seems to possess the greatest margin of safety and simultaneously affords a high curative index. In addition it is applicable to ambulatory patients.

It is unfortunate that Drs. MacKee and Astrachan have been unable to follow more of their patients over a greater period of time. This is always a most difficult problem. At Bellevue I think we have been remarkably successful. Of course, we hospitalize all patients and have facilities available for simultaneously treating 200. In small groups these patients receive instructions regarding their disease and information concerning what we are trying to do for them.

Every effort is made during the patient's stay in the Hospital to secure his confidence. During his stay much information is obtained which might be of assistance in subsequently tracing him. This includes the names and addresses of friends and relatives, the referring agency, place of business, names and addresses of unions, churches attended, and clubs, draft board, home relief, WPA, driver's or chauffeur's licenses, auto registration number, social security number, and criminal record. Even with all this information it is often impossible to trace delinquents.

Dr. Cannon and his collaborators have presented a concise and complete review of intensive arsenotherapy, including a brief reference to the earlier investigators in this field. Many of the early favorable responses to intensive therapy must be taken reservedly because of lack of satisfactory diagnostic criteria and complement fixation tests of sufficient sensitivity and specificity.

I am surprised at the lack of serious accidents in the ten-day treatment in which 120 mg. of mapharsen is given daily. Of course, only about 80 patients are reported and a more extended series may afford

more reactions. According to our experience at Bellevue Hospital and the recorded experiences at the Chicago Rapid Treatment Center, reactions are much higher. In a series of 172 patients so treated at Chicago, 11.9 per cent of reactions were so serious that it was necessary to modify the schedule by reducing the mapharsen dosage by half. Cole, of Cleveland, in a series of 114 patients with an eight-week, and 95 with a ten-week schedule, in which 34 patients were lost from observation, in 24 or 14 per cent it was necessary to discontinue therapy because of reactions. Drs. MacKee and Astrachan had reactions sufficient in severity to require discontinuation of treatment in about 8 per cent of cases. It is interesting that no one reports a serious toxicoderma.

I still feel that patients should preferably be hospitalized for intensive therapy. If this is so, I believe the technic employed by Drs. Thomas and Wexler at Bellevue Hospital gives excellent results with a minimum of reactions. Briefly, this consists of ten daily injections of mapharsen (60 mg.) plus intravenous typhoid-paratyphoid vaccine on the second, fourth, sixth, and eighth days.

Under the schedule of treatment with arsphenamine, in which series 29 patients were treated at the Vanderbilt Clinic, 23 of whom were in the secondary stage, Dr. Cannon stated that all spinal fluids were negative at the beginning of treatment. Does this mean they were normal? If so, is not this unusual in an unselected group of patients with florid syphilis? The Cooperative Clinical Group found abnormal fluids in 56 per cent of patients with secondary syphilis.

I think all of the essayists should be congratulated on their valuable contributions to intensive arsenotherapy.

Dr. Girsch D. Astrachan, *New York City*—I wish to thank Dr. Combes and Dr. Rosenthal for their constructive criticisms. I agree with both of them that all the intensive methods which are in use are still in the experimental stages, and years will pass before we will come to any conclusion concerning their value and importance.

The main thing which we ought to remember is that in every intensive procedure which has been tried to date, between 1,200 and 1,800 mg. (total amount) of mapharsen, or about 20-30 mg. per kilogram of weight had to be given in order to achieve a so-called "cure."

It is also important to remember that a margin of safety of 6-8 is necessary to reduce the mortality of antisypilitic therapy to less than 1:1,000. This margin of safety would be provided by giving the total curative dose in triweekly injections for seven weeks. I believe that a mortality rate of 1:1,000 is the maximum number of fatalities which we may be justified in expecting even with the intensive method of treatment.

I agree with Dr. Combes that post-treatment observation is of paramount importance for further evaluation of therapy. It is, however, a very difficult problem, and in spite of the excellent work done by the social service department we could not follow up all of the cases.

I was glad to hear the discussers place so much

emphasis on the use of bismuth in antisyphilitic therapy. I have always believed in the concurrent administration of bismuth and arsenicals in young and healthy individuals.

The majority of our patients were hospitalized in the Metropolitan Hospital, however it is very difficult to keep patients in a hospital for more than a few weeks, but we did manage to keep about half of them for the entire course of therapy.

I was very much interested in Major Weitz's discussion of the Army schedule of treatment. It is an excellent method and it seems to me that this procedure or a modification of the one of Eagle and Hogan will probably turn out to be the best method of antisyphilitic therapy for the general practitioner to use.

We still don't understand, as Dr. Thomas pointed out, the causes of the so called resistant serologic reaction. It is quite a problem but I don't believe it

is very serious in late latent cases. I do feel, however, that at least two years of treatment should be given in order to prevent various kinds of complications due to late latent syphilis.

I was very happy to hear Dr. Rosenthal's plea for consideration of the patient first and the technique last, and I am in full agreement with him. It seems to me that the physician should have a frank discussion with the patient on the various methods of treatment, their dangers, advantages, and disadvantages, and the patient will then be able to decide which method he prefers. Most patients are quite capable of deciding for themselves whether they prefer the rapid method with the possible chance of serious complications, or the longer, tedious, but safer method of therapy. It should be the patient's privilege to select the manner in which he is to be treated.

### LASKER FOUNDATION ESTABLISHES MENTAL HYGIENE AWARD

Dr. George S. Stevenson, Medical Director of the National Committee for Mental Hygiene, has announced that the Albert and Mary Lasker Founda-

It will be conferred at the annual meeting of the Committee in the autumn of each year.

The purpose of the award is to recognize significant contributions to promoting mental health and to making the broad field and program of mental hygiene more familiar to the general public. Each year the award will be made for a contribution in some special aspect of the field of mental hygiene which seems to be of most immediate and current significance. The recipient of the award will be selected by an anonymous jury chosen annually for its competence to judge accomplishment in a particular field.

The award went this year to Col. William C. Menninger, MC, Chief Consultant in Neuropsychiatry, Office of the Surgeon General, U.S. Army. It was presented by Brig. Gen. Raymond W. Bliss, Assistant Surgeon General, U.S. Army.

The award this year was for mental hygiene

work related to the war. The recipient was chosen from among leaders who have done work in the general enhancement of the mental health of the men and women of the services, both while in service and during the period of rehabilitation. The work must either have been completed or have been tested and won general acceptance within the year preceding the granting of the award. Recipients will not necessarily be limited to persons in the United States.

If some outstanding contribution has been made abroad in a particular field, the award will be made jointly with the leading mental hygiene organization of that foreign country.

The Award Committee consists of Dr. Lawrence S. Kubie, chairman, Dr. Frederick H. Allen, and Miss Nina Ridenour. This committee determines the scope and method of granting the award and selects a jury of seven to nine to name the recipient.

The range of activities for which the award will be made will include psychiatric education, popular adult education (through books, articles, lectures, and plays), and popular child education (in schools, camps, playgrounds, community centers, churches and other group activities).

### AGAR STOCKPILES ARE GROWING

Stockpiles of agar, formerly dependent on supplies received exclusively from Japan, have now been improved to such an extent by newly developed domestic production and by imports from Mexico that restrictions on the use of agar have been removed, the War Production Board reported on August 14.

Agar is a jelly-like substance extracted from certain types of seaweed found on both the Atlantic and Pacific coasts. It is principally used in making bacteriologic culture media, but only the seaweed found on the West Coast yields the type of agar that can be used for the production of these media. Agar is also used in the preparation of medicinals,

pharmaceuticals, and food, and in the drawing of tungsten wire and the manufacture of dental impression compounds.

Domestic production of agar was accomplished as a result of close cooperation between industry and the Chemicals Bureau of WPB. The largest agar plant is situated in Los Angeles, California. Smaller agar production units have been established in Massachusetts, Virginia, the Carolinas, and Florida.

To insure fulfillment of any emergency needs for agar, a stockpile is being reserved by the Defense Supplies Corporation, a subsidiary of the Reconstruction Finance Corporation.

# THE EVALUATION OF NEWER DRUGS IN OPHTHALMOLOGY

WALTER S. ATKINSON, M.D., Watertown, New York

**I**N AN attempt to evaluate drugs used in ophthalmology not only the properties of the drugs but the medium in which they are given and the method of administration should be considered.

Buffered solutions, wetting agents, and iontophoresis have been shown to increase as much as fifteen times the penetrability and effectiveness of drugs used in the eye. Therefore, with the same drug quite different results may be obtained and erroneous conclusions may be arrived at by different observers if the drugs are not used in the same manner.

A brief consideration of a few well-known principles with respect to the method of using drugs in the eye may be of value.

Solutions isotonic with the tears cause less irritation when instilled in the eye than strongly hypotonic solutions. However, it is probably of more importance to have the reaction or pH correct for the solutions to be used in the eye. The advantages claimed for properly buffered drugs when instilled in the eye are:

1. They are more readily absorbed, which increases their action.
2. They smart less.
3. They are more stable, so that fungi and bacteria rarely grow in them.
4. Conjunctival congestion occurs less frequently after the prolonged use of drugs such as pilocarpine or physostigmine.

The pH of tears may vary with different diseases of the eye. It is sometimes desirable to test the pH of the tears before prescribing a solution to be used in the eye. This may be quickly approximated with nitrazine or similar paper.

In conditions that cause an acid lacrimal secretion an alkaline solution may be desirable. When the tears are alkaline, as they are in corneal injuries, an acid buffer solution often affords considerable relief.

In prescribing drops to be used in the eye, it is not practical to incorporate with each prescription the directions for buffering the drug. Therefore, if the pharmacist follows the simple directions suggested by Gifford<sup>1</sup> the drugs can be easily and satisfactorily buffered. Two solutions only are necessary to keep on hand, and they are as follows:

## Acid buffer solution:

Boric acid (anhydrous).....12.4 Gm.

Potassium chloride (anhydrous).. 7.4 Gm.

Distilled water.....1,000 cc.  
Stock solutions of sodium carbonate:  
Sodium carbonate (anhydrous)...21.2 Gm.  
Distilled water.....1,000 cc.

The desired reaction, varying from a pH of 5 to 9, may be obtained by the addition of different amounts of the stock solution of sodium carbonate to 30 cc. of the acid buffer solution, as shown in Table 1.

The selection of the buffer for the various drugs used in the eye is governed to some extent by the solubility of the drug. If possible, however, a buffer that causes the least irritation should be used.

By adding 1.5 cc. of the stock sodium carbonate solution to 30 cc. of the acid buffer solution in alkaline buffer solution with a pH of 7.6 is obtained. Gifford<sup>1</sup> recommends this for use as a collyrium and as a substitute for tears in mild epithelial dystrophy and chronic conjunctivitis in elderly persons. It has a soothing effect when instilled in the eye and is mildly antiseptic. Also, it is the buffer recommended for homatropine, atropine, scopolamine, physostigmine, and pilocarpine.

Tetracaine (pontocaine) hydrochloride comes in tablets already prepared so that a buffer is not required. When the tablet is dissolved in distilled water the solution has a pH of 6.7. A pH of 6.0 is recommended for zinc sulfate, cocaine, epinephrine, and paradrine. A buffer with a pH of 9.0 is required to dissolve fluorescein.

Wetting agents have been shown to greatly increase the penetrability of drugs through the cornea and thus improve their effectiveness. Bellows and Gutman<sup>2</sup> reported a marked increase in the concentration of the sulfonamide compounds in the aqueous by the use of wetting agents. Aerosol OS (isopropyl naphthalene sodium sulfonate), 0.5 to 1.0 per cent, was found to be the most effective one, and, they reported, increased the ability of sulfathiazole to penetrate the cornea and produced a concentration over fourteen times greater in the aqueous humor. It was also noted that local and systemic heat further increased the penetration of the sulfonamides by as much as 50 to 75 per cent.

These are important observations since, as pointed out by Bellows and Chinn,<sup>3</sup> the sulfonamide compounds, with the exception of sulfanilamide, penetrate the cornea poorly. Their studies have also shown that a higher concentration of the sulfonamide compounds is obtained in the anterior chamber by local application when

TABLE 1

Amount in cc	0	0.05	0.1	0.25	0.50	1.00	1.50	2.00	3.00	4.00	8.00
Reactions (pH)	5.0	6.0	6.2	6.75	6.95	7.2	7.6	7.8	8.2	8.4	9.0

they are used with wetting agents than from oral administration.<sup>2</sup> However, both local and general administration should be used when the highest concentration is desired. The use of wetting agents also improves the penetrability of other drugs, such as local anesthetics, antiseptics, and drugs used in the treatment of glaucoma and is a subject worthy of serious consideration.

The use of iontophoresis to obtain higher concentrations of the sulfonamide compounds in the cornea and aqueous humor has been reported by von Sallmann<sup>4</sup> and Boyd.<sup>5</sup> By iontophoresis von Sallmann<sup>4</sup> was able to increase the concentration of sulfadiazine in the aqueous humor as much as fifteen times more than by means of a corneal bath. By this method the concentration of sulfapyridine and sulfacetamide was also greatly increased in the cornea and aqueous humor. Boyd reported that the amount of sulfathiazole introduced by iontophoresis into the cornea was four times greater and in the aqueous five to nine times greater than by simple diffusion.

Another most interesting observation made by von Sallmann<sup>4</sup> is that the sulfonamide drugs penetrate the cornea more readily when it is ulcerated or abraded. The concentration in the cornea, aqueous humor, and vitreous humor is two to three times more than when the cornea is normal.

More recently von Sallmann<sup>6</sup> reported that six to nine times more atropine and scopolamine were introduced into the aqueous humor of rabbits by corneal iontophoresis than by a two-minute corneal bath. Unfortunately, iontophoretic application to the sclera did not increase the concentration in the vitreous.

By means of iontophoresis von Sallmann<sup>4</sup> obtained higher concentrations of the sulfonamides in the aqueous humor than those reported by Bellows and Gutman<sup>2</sup> with the use of wetting agents. However, wetting agents are easier to use, particularly for postoperative infections, than iontophoresis and so would be preferable provided an effective concentration can be obtained without damage to the cornea or lens.

In the consideration of newer drugs used in ophthalmology it is realized at once that few really new drugs have been introduced during the past few years.

Penicillin is thought of at once, and, although it was discovered by Fleming<sup>7</sup> fifteen years ago, its use as a therapeutic agent is new. Comparatively little penicillin has been available for use

by ophthalmologists, so that its true worth in the treatment of diseases of the human eye is difficult to accurately appraise. However, reports of its use experimentally by von Sallmann<sup>8</sup> in the treatment of intraocular infection is most encouraging. His report justifies the anticipation that striking results may be expected in the treatment of infections which are now considered hopeless.

Tyrothricin, a substance obtained from soil bacteria which shows marked bactericidal powers for gram-positive organisms, has received comparatively little attention by ophthalmologists. Heath<sup>9</sup> reports that he obtained the most favorable results in the treatment of epidemic keratoconjunctivitis with the local use of 30 mg. of tyrothricin per 100 cc. four to six times daily.

He also recommends its use in the treatment of pneumococcal conjunctivitis (except Friedlander's type), dendritic keratitis, and low-grade dacryocystitis. My experience with tyrothricin, though limited, has been disappointing.

In the field of anesthesia, many new local anesthetic agents have been produced since the introduction of cocaine.

Tetracaine (pontocaine) hydrochloride is a good representative of the newer group. The chief advantages of tetracaine are, it smarts very little when it is instilled in the eye, its action is rapid and prolonged, the pupil is not dilated, it does not influence the tension, nor is the accommodation affected. Tetracaine does not cause desiccation of the corneal epithelium nor devitalize the cornea. Patients are rarely sensitive to tetracaine but this possibility should be kept in mind.

All local anesthetic agents probably delay healing of the corneal epithelium to some extent but in a recent study by Gundersen and Lieberman<sup>10</sup> 0.5 per cent tetracaine hydrochloride was found to be one of the least toxic to the regenerating epithelium.

Although there have been many new local anesthetic agents produced for infiltration and block anesthesia, procaine hydrochloride (novocaine) is still generally conceded to be the anesthetic of choice for injection.

Pentothal sodium used intravenously for the production of general anesthesia in ophthalmology is becoming increasingly more popular. The rapid induction and prompt recovery with comparatively few undesirable complications, when skillfully used, make it an excellent anesthetic

for many eye operations that require general anesthesia. Pentothal sodium may be used for induction. It is compatible with other anesthetic agents and can be used in conjunction with them or to supplement local anesthesia.

As with all general anesthetics, there are definite contraindications, which experience with its administration have minimized. One contraindication is physiologic or mechanical interference with the respiratory function. The importance of the use of atropine in the preanesthetic medication should be emphasized. An experienced anesthetist is essential, and equipment should be at hand to administer oxygen by inhalation or by insufflation, if necessary. Careful postoperative observation by a competent person equipped to cope with serious apnea is advisable. Occasionally, venipuncture is difficult or not practical.

In a series of eye operations performed with pentothal sodium reported by Post and Robertson,<sup>11</sup> 23 per cent of the patients vomited. Falls,<sup>12</sup> in a series of 147 ophthalmic operations done with pentothal sodium, reported vomiting in over 17 per cent. Such a high incidence of vomiting would indicate that globe operations such as cataract extractions would be safer with local anesthesia.

As with the anesthetic agents, there have been many antiseptics produced in recent years. In choosing an antiseptic the principal consideration is the rapid destruction of the infective organism with a minimum of tissue damage. Furthermore, the antiseptics which have an injurious effect upon the natural defense processes, such as the leukocytes and lysozyme, should be avoided. Also of importance is the ability of the antiseptic to penetrate the tissues, so that it will reach the infective process in sufficient concentration to be of value.

Many excellent antiseptics are now available that fulfill the majority of these requirements. Aqueous solution of metaphen (4-nitro-anhydroxy-mercury-ortho-cresol), 1:2,500, is a good example of this group. The phenol coefficient is high, and it causes little tissue damage and practically no irritation when instilled in the conjunctival sac. For preoperative skin disinfection 1:200 tincture of metaphen or 1:1,000 tincture of merthiolate (sodium ethyl mercuri thiosalicylate) is preferred rather than tincture of iodine, not because tincture of iodine is inferior but because some of the newer antiseptic agents used in the eye are not compatible with tincture of iodine.

To combat infections at the present time, however, our thoughts turn at once to the sulfonamides and penicillin even though the latter is still out of reach of most ophthalmologists.

Two years ago, Thygeson and Stone<sup>13</sup> pre-

sented a paper before the Section on Ophthalmology on sulfonamide therapy of ocular infections. Therefore, little need be said in regard to the sulfonamides except to emphasize a few points concerning their use. It is generally agreed that the nonspecific use of the sulfonamides should be avoided. The selection of the drug, whenever possible, should be based upon a precise knowledge of the organism present and the sulfonamide compound chosen that has the greatest bacteriostatic effect on this particular organism.

Bellows<sup>14</sup> has reported that in the absence of normal epithelium the sulfonamide compounds not only injure the cornea but the regeneration of epithelium is greatly retarded. Therefore, the routine use of the sulfonamides locally for minor injuries of the cornea and as a postoperative medication is contraindicated, because it delays healing.

Since the penetrability of the sulfonamide compounds varies greatly, particularly in regard to the eye, it is essential to select the compound that penetrates the ocular tissues most readily in order to maintain a sufficient concentration of the drug in the affected part. Also of great importance is the use with the sulfonamides of wetting agents to reduce the surface tension. The disturbance of the corneal epithelium caused by local anesthetic agents, particularly cocaine, also allows the drug to penetrate more easily. Heat, both local and general, and massage as well as other measures to increase the penetrability and effectiveness of the drugs may be used.

In regard to the size of the dose, the consensus of opinion is that, in most instances, a large dose of the sulfonamides for a short period is preferable to a small dose over a long period. Inadequate concentrations of the drug not only may be ineffective in combating the infection, but may produce hypersensitization or a sulfonamide-fast organism. Frequent estimations of the blood level of the sulfonamides should be made, since it is essential to maintain an adequate concentration in the blood if the purpose of the treatment is to be accomplished.

In the treatment of glaucoma, prostigmine has been found to be a most useful addition to the list of miotics. Clarke<sup>15</sup> suggested its use with mecholyl; the mecholyl to stimulate the sphincter directly, and the prostigmine to inhibit esterase from destroying both the mecholyl and the normally produced acetylcholine. Alarming general reactions which occasionally occur with mecholyl discourage its use. However, prostigmine alone or with other miotics aids greatly in the treatment of both acute congestive and non-congestive glaucoma.

The pharmacologic action of prostigmine is

similar to that of physostigmine (eserine) but has a much stronger miotic action. Fewer patients become sensitive to prostigmine and it does not deteriorate as rapidly as physostigmine.

Along with the usual treatment of acute glaucoma, instillations of 5 per cent prostigmine every ten to fifteen minutes for four to six instillations usually reduces the intraocular pressure to within normal limits.

In noncongestive glaucoma where the fields, vision, and intraocular pressure are not controlled with pilocarpine, and operation is either contraindicated or postponed, prostigmine is of value. As with other miotics, the solution of prostigmine should be no stronger than is necessary to satisfactorily control the glaucoma. It may be used to supplement the action of pilocarpine or in the place of pilocarpine or physostigmine should the patient become sensitive to either. When the use of prostigmine is first begun, it may cause pain in the eyes and head which is generally relieved with an A S A compound tablet (acetylsalicylic acid, acetophenetidin, and caffeine). The pain rarely occurs after the second or third day of treatment. Occasionally, patients are sensitive to prostigmine, as they are to other drugs used in the eye.

Carbaminoylecholine chloride (doryl) is a synthetic choline derivative, similar to acetylcholine but it has a more prolonged action. According to Guyton,<sup>16</sup> it produces a miosis comparable to that of pilocarpine of the same strength. Since it does not penetrate the cornea well, O'Brien and Swan<sup>17</sup> recommended using it in a 0.03 per cent solution of zephiran chloride, which acts as a surface tension-reducing agent and thus increases the corneal permeability. Later Swan<sup>18</sup> reported that a suspension of carbaminoylecholine chloride in petrolatum penetrates the cornea more readily and its action is more rapid and effective than when used in aqueous solution or in a solution of zephiran chloride. Massage of the cornea through the lids further increases the absorption.

In the comparison of 1.5 per cent carbaminoylecholine chloride in 0.03 per cent zephiran chloride solution with 2 per cent pilocarpine nitrate solution, it was found that carbaminoylecholine produced slightly greater miosis and lasted approximately three times as long as that produced by pilocarpine.<sup>15</sup>

Therefore, less frequent instillations of carbaminoylecholine are necessary to control the glaucoma. It produces a hyperemia of the conjunctiva which may be quite marked at first. Pain in the eye and headache may also be noted following the initial administration, but, as with prostigmine, it only occurs during the first few days of treatment.

Often the intraocular pressure in acute con-

gestive glaucoma is not sufficiently reduced by miotics to permit an operation to be done safely. Various intravenous injections have been advocated to lower the intraocular pressure by osmosis. Hypertonic sodium chloride solution, dextrose, and sucrose have all been used but there are definite objections to their use. Hypertonic salt solution produces edema and is contraindicated in patients with cardiac and renal damage. The salt also enters the anterior chamber of the eye and causes inhibition of water absorption with a secondary rise of pressure, often higher than it was originally. Furthermore, if it is extravasated into the tissues, it produces a slough. Dextrose, like sodium chloride, is readily diffused in the ocular tissues and produces a secondary rise in pressure after an initial drop. Its use is limited to nondiabetic patients. Sucrose was later introduced, since it did not have many of the disadvantages of hypertonic salt solution and dextrose, but it has been discontinued because it produces renal damage.

Sorbitol has been reported by Bellows *et al.*,<sup>19</sup> as the best agent readily available that does not have these objectionable qualities. It is nontoxic, effective in moderate quantities, and is not contraindicated in persons with diabetes. In acute glaucoma with high intraocular pressure the intravenous injection of 50 cc to 100 cc of 50 per cent solution of sorbitol produces a marked decrease in the pressure. This may occur as early as two hours after the injection, but the maximum effect is reached in from twelve to twenty-four hours. The pressure may rise again if the injection is not repeated or an operation performed to control it.

The conclusion reached after this brief evaluation of newer drugs used in ophthalmology is that the method of administration is of paramount importance if the full effect of the drug is to be obtained.

## Discussion

Dr. Albert C. Snell, *Rochester*—Dr. Atkinson has presented many practical suggestions on the proper use of some of the newer drugs. He has laid particular emphasis on methods of application which make their use more efficient. These methods relate to the use of buffer solutions and of "wetting" methods. I can add to this valuable paper only some of my personal experiences in the use of these drugs and in methods of application.

Dr. Atkinson leads one to believe that the compounding of the proper buffer for various ophthalmic solutions is a simple and easy matter. I find that this idea needs some modification. From inquiries of pharmacists I find that buffering is not simple and that only a small minority of the best pharmacists can be trusted properly to buffer solutions.

Therefore, if the ophthalmologist desires to have a properly buffered solution, it is wise for him to consult with the druggist and select a dependable one; most will not be bothered with buffering.

To point out the difficulties in buffering and to make clear the conception of the meaning of pH, I venture to add the following: If one can think of a scale of pH values as a scale running from 1 to 14, the center of which indicates a neutral solution, then 7 will be this neutral point. The pH values below the 7 indicate acidity, whereas the pH values above the 7 indicate alkalinity. Thus, if the pH of any solution is known, and one wishes to have the solution acid, or alkaline or neutral, it is possible to buffer the solution as desired following the steps mentioned by Dr. Atkinson.

Some of the difficulties of buffering can be understood when one realizes several factors:

1. How delicate the balance between acidity and alkalinity is. For this reason, in order to make the proper basic solutions, either the acid or the alkaline, the pharmacist must use at least 1,000 cc. of fluid, and some authors recommend 10,000 cc. Therefore, there is considerable waste if the pharmacist is not constantly compounding the buffered solutions.

2. The buffered solution is not altogether stable.

3. Another difficulty is encountered because sterile distilled water, when freshly made, has a pH of 7, which is neutral, but it rapidly becomes acid, and the pH may drop to 5.7. This is caused by absorption of carbon dioxide. Therefore, freshly made solutions are very important, and under all circumstances the pharmacist should repeatedly test the pH by some standard method. The colorimetric method is practical and satisfactory, and stock solutions must be constantly retested if the desired pH is to be maintained. All this adds to the expense of a buffered solution but is often worth while in some solutions. For example, the use of a buffered solution having a pH of 7 to 8 is most valuable in applying contact lenses, and with the drugs mentioned by Dr. Atkinson.

In prescribing a buffered solution one should designate the pH desired. If neutral, state a pH of 7.4, which is the pH of normal tears. If one desires the solution to be slightly acid, designate that the solu-

tion should be pH 6; if alkaline, the pH should be 7.5 to 8.

The most efficient ophthalmic solution is not always a neutral solution, as some drugs act better in an acid pH, others in an alkaline, and still others require a specific pH. But in general, the least irritating solutions are those which have the same pH as tears. However, the pH of tears differs with the individual. Since some bacteria cannot live in an acid medium, while others cannot live in an alkaline medium, a pH should be prescribed which is known to be most effective. For example, the pneumococcus cannot live in a medium with a pH of less than 7, and therefore should be treated with an acid solution. For streptococcus infection an alkaline buffered solution is indicated, but an alkaline solution is contraindicated in the treatment of gonococcus infection, where the pH should be below 5. For the treatment of vernal conjunctivitis the buffer should have a pH of 8.4.

In reference to some of the newer drugs mentioned by Dr. Atkinson, I wish to remark that my experience with pentothal sodium has been most satisfactory. In the last twenty enucleations we have had no cases of vomiting and practically no distressing symptoms. However, this anesthetic has been given only to adults. We are informed that it is less satisfactory with children, with whom there is additional risk.

I have had no experience with the use of aerosol and I would like to ask Dr. Atkinson if he advises the use of this drug with all antiseptics.

For the treatment of glaucoma I used doryl in a limited number of cases but found it ineffective. Furthermore, a government agent confiscated what I had left. As an adjunct to other forms of treatment of glaucoma, I have had very good results with 5 per cent prostigmine bromide. This has been especially effective when the tension could not be entirely controlled by operation, in senile patients, and in some cases of glaucoma following cataract extraction. In these types of cases I have found that the instillation of prostigmine fifteen minutes prior to the instillation of pilocarpine is most effective.

Among the sulfa drugs I have found sulfamerazine to be most practical, when the sulfa drug is to be administered orally. With this drug an efficient blood level can be maintained with half of the indicated dose for sulfathiazole.

Dr. Ludwig Sallmann, *New York City*—First I would like to thank Dr. Atkinson for the generous credit he has given the experimental work done in the Knapp Memorial Laboratory and also for the chance to read his excellent paper before its presentation. This has enabled me to check some figures pertinent to the problem of wetting agents and iontophoresis and to conduct a series of experiments comparing the effectiveness of the two methods.

Bellows and Gutman stated that in the use of wetting agents a simple method is at hand for increasing the concentration of sulfonamide in the cornea and aqueous humor, making the more complicated method of iontophoresis unnecessary. In my opinion, evidence presented so far does not seem to fully

justify this statement. About 40 mg per cent of sulfadiazine is found in the aqueous humor one hour after a single iontophoretic treatment. Bellows and Gutman report an average of 4.4 mg per cent of the same compound in the aqueous humor after an hour's application of a paste containing the sulfonamide and the wetting agent aerosol OS. The same is true, although to a lesser degree, of comparative figures with sulfapyridine and sulfathiazole. In a new series of experiments, various amounts of aerosol OS were added to a 5 per cent solution of sodium sulfacetamide and the concentrations of the sulfadiazine in the aqueous humor one hour after a five-minute bath with these solutions were compared to those found after iontophoresis. A great increase in the permeability of the cornea resulted from the use of the wetting agent in a 0.1 per cent concentration but also that there was considerable damage to the cornea and irritation to the anterior segment of the eye lasting for several days. When only a 0.02 per cent aerosol solution was used, damage was apparently avoided but the amount of the sulfonamide reaching the anterior chamber was moderate. The simple instillation of a local anesthetic, namely 0.1 per cent nupercaine hydrochloride, was considerably more effective in securing a larger amount of the sulfacetamide in the aqueous. When iontophoresis was used with the same local anesthetic, the concentration of the sulfonamide in the aqueous

went up to more than 40 mg per cent, about thirty times higher than in control eyes treated with corneal bath under general anesthesia.

At the present time, therefore, it seems very unlikely that the permeability of the cornea can be greatly increased by the use of wetting agents without causing considerable damage. The principal advantage of this new technique would be in the maintenance of an increased but moderate drug level in the structures of the anterior segment of the globe, provided repeated applications could be given daily. However, experiments on chronic toxicity of the wetting agents have not been reported as yet. They appear indispensable in view of the irritation seen in rabbits' eyes after the frequent use of penicillin ointments and solutions containing wetting agents of the aerosol group when continued for three hours. In conclusion, more experimental work is necessary to establish a safe and effective dosage of these surface detergents in ocular therapy.

In regard to penicillin, I would like to make a brief statement. Experimental work carried on in the last half year has revealed that direct injection of small amounts of purified penicillin into the anterior chamber, lens, or vitreous seems to constitute a reasonably safe therapeutic procedure to fight acute exogenous infections of the eye. This observation is of foremost importance for the infective foci which cannot be reached by the drug in other ways.

#### HOSPITALIZATION FOR INFECTIOUS TUBERCULOSIS

The public health and social benefits resulting from the hospitalization of infectious cases of tuberculosis are not sufficiently recognized. These social benefits need greater emphasis and the

question of the individual's ability to pay should be subordinated to the more fundamental consideration of the public welfare.—Robert E. Plunkett, M.D., *N.Y. State Dept. of Health Annual Report, 1942*

#### M.D. License Plates

Physicians desirous of having M.D. license plates reassigned to them for 1945 are advised to make out application blanks at once on forms now available at the Motor Vehicle Department offices and other places throughout the State.

The application blank should be accompanied by a check and also contain a note on the physician's letterhead requesting the M.D. license plates because the holder of same is a practicing physician.

License plates for 1945 will be available shortly after December 1, 1944.

Please give this your prompt attention.

PETER IRVING, M.D., *Secretary*

# THE MANAGEMENT OF OBESITY

LOUIS PELNER, M.D., Brooklyn, New York

**D**URING the past year, a reducing fad popularly called the "technicolor" method has become very popular with both physicians and patients in this part of the country. The word "technicolor" refers to the three differently colored tablets that are dispensed to the patient by the physician, one to be taken before breakfast, one before lunch, and one at 4:00 o'clock in the afternoon. Each tablet contains approximately the following constituents: 5 mg. of amphetamine or benzedrine sulfate,  $\frac{1}{320}$  Gm. of atropine sulfate, and 1 grain of thyroid extract. In addition, the morning tablet contains a small dose of aloes, while the evening tablet contains phenobarbital. Often phenomenal weight loss is said to occur during the first two weeks of therapy. However, soon afterward the weight loss ceases because the patient has become refractory to the medication, and once again he becomes disillusioned.

It is the purpose of this paper to show the inherent faults in this shotgun prescription, and to show how the physician can utilize the principle of appetite depression to safely reduce those overweight patients who require it. For the appetite depression, both benzedrine sulfate and atropine sulfate are used in slowly ascending doses, changes being made about every two weeks. In this manner patients who become relatively refractory to certain amounts of this drug can keep on losing weight.

A detailed report with graphs and a discussion of the mode of action of benzedrine sulfate and atropine sulfate is given elsewhere.<sup>1</sup> Here it will suffice to discuss the principles and dosage underlying the appetite-control method of the treatment of obesity.

The most common and important type of obesity is without doubt caused by overindulgence in food. The thyroid gland is seldom involved as a cause of obesity. In hypothyroidism, fat is not greatly increased in the patient. Instead there is a peculiar form of fluid present, as is evidenced by the term "myxedema." There are, however, fat deposits on the neck and shoulder, but these are not extensive. It is often stated that the basal metabolic rate in obese patients is low, and therefore they have hypothyroidism. Greenhill<sup>2</sup> points out that the basal metabolic rate as ordinarily determined is the total basal metabolism, and takes

into consideration actively oxidizing tissues as well as the inactive tissues, such as fat deposits. Since in obese individuals these inert deposits predominate, they weight the basal metabolism in a negative direction. If we should calculate the basal metabolism on the ideal weight basis, most obese individuals would have high metabolic rates. This author points out the futility of giving thyroid to most of these patients, when their tissues are already burning at a high rate. The shotgun "technicolor" method of weight reduction does not take into consideration this important point.

In many cases, at least, overeating may be due to a psychic disturbance in which the individual is unprepared to meet the social demands of everyday life. Thus overeating is indulged in, and obesity results. Bruch<sup>3</sup> has done a great deal of work on this subject in children. She has found that many overweight children are unhappy and maladjusted. Glandular treatment under these conditions is not only useless, but harmful. The treatment is psychotherapy and diet. Greenhill<sup>2</sup> goes into the social, economic, and psychic factors that cause people to overeat. An individual may have grown up in an environment where a great deal of food is eaten. He thus continues this practice of gluttony in later life, and the consequence is overweight. The overeating may be an escape mechanism for a mental conflict. There is also a group of people who lack interests in life and obtain pleasure in overeating. It is often impossible to appease their appetites because they are unable to satiate their sensory desires (anhedonism). Another form of mental conflict, considered important in females, is that obesity can be an escape from competition for masculine attention. In this condition overeating is an excuse. It can thus be seen that in addition to any treatment outlined, psychotherapy, especially of the family-physician type, must also be used in conjunction with any form of treatment. It can also be seen why such divergent reports appear in the literature on any form of treatment. It is impossible to formulate statistical results on these patients because of the psychic elements involved, and because of the varying abilities of different investigators in performing psychotherapeutic treatment.

The first and foremost principle in the treatment of obesity is the placing of the patient on a low calorie diet (e.g., 1,000 calories). If this can be adhered to, no other treatment is required (See Chart 1.)<sup>4</sup>

<sup>1</sup>Associate attending physician, Greenpoint Hospital; assistant attending physician, Long Island College Hospital and Brooklyn Cancer Hospital; gastroscopist, Beth Moses Hospital, Brooklyn.

CHART I.—ILLUSTRATIVE DIET LIST

Your total calories should not exceed for each day. Divide them as directed below Do not eat between meals. Some exercise must go with this diet daily

## BREAKFAST

You may select from below	calories	Calories
Calories		
25		50
20		125
45		70
50		35
75	1 teaspoonful sugar	25
75	1 plain cracker	20
75	Tea or coffee with no sugar	0

## LUNCH

You may select from below	calories	Calories
Calories		
20		25
20		25
15		25
15		25
15		20
30		40
50		35
100		55
65		40
75	Tea or coffee with no sugar	0

## DINNER

You may select from below	calories	Calories
Calories		
75		80
85		60
90		75
85	1 egg	75
85	1 piece haddock (2 × 3 inches)	35
85	6 large oysters	40
95	1 piece brook trout	45
75	Tea or coffee with no sugar	0

Bread, beverages, fruit, etc., from the above list, may be added to any meal provided the total calories do not exceed the amount prescribed.

The following foods must be avoided. Nuts, olives, olive oil, chocolate and cocoa, gravies, cream soups, sauces, ice cream, candy, pastry, macaroni, potatoes, alcoholic beverages, canned fruits in syrup, and highly spiced and salted foods. Do not use sugar unless you absolutely have to.

Four glasses of water each day are allowed. Be sure that your daily menus include a fresh fruit, either meat, fish, or egg, milk, and three vegetables.

The calories may be divided as follows: 150 for breakfast, 250 for lunch, and 600 for dinner. This division may be varied according to the patient's desires.

It has been found by experience that merely admonishing a patient to adhere to a low calorie diet has been largely unsuccessful. This has been true even though the patient may be sincere in his attempt to lose weight, because adherence to a low calorie diet alone will often cause intense weakness. This may be present even though vitamin and iron medication is indicated.

For this reason it is necessary to employ means that will curtail the appetite and at the same time would give the patient a feeling of well-being that will encourage him to continue the dietary treatment. The appetite depressants used in this study were benzedrine sulfate<sup>6,7</sup> (racemic amphetamine) and atropine.<sup>8,9</sup> The dosage of benzedrine was usually started at 5 mg. three times a day, and increased slowly at two-week intervals to about 10 mg. three times a day. Occasional cases required 12 mg. three times a

day. This substance was combined with atropine, in doses starting at  $\frac{1}{100}$  of a grain and gradually increased to  $\frac{1}{200}$  grain. These drugs were given together in a capsule one hour before each meal. A tolerance was soon developed for each of these drugs, so that the same dose would no longer cause a reduction in appetite. It was therefore necessary to increase the dosage of either or both of them, about every two weeks. Thyroid was included if the basal metabolic rate was below minus 5 per cent. The dose of thyroid, which, when used, was also included in the same capsule, ranged from  $\frac{1}{8}$  of a grain to 1 grain three times a day. The appetite-depressing medication was found to work best when taken about one hour before meals. Most women did not lose weight around their menstrual periods. This is a well-known concept and is undoubtedly due to retention of water at that time. Under such conditions aminophylline in 3-grain tablets was given three times a day, to tide over the period of fluid retention. This often caused a satisfactory reduction in weight. Occasionally mercupurin or mercuhydrin, a new

mercurial, was used if aminophylline was found to be ineffective.

It was invariably found that even though weight loss had been satisfactory for several months, a point was reached when the patient became refractory to both benzedrine and atropine. This is a phenomenon that has been noted with most patients receiving these autonomic drugs. Under these conditions, it was necessary to discontinue the medication. In order for the subject not to increase his weight again, it was decided to have the patient take a gel-producing substance, such as metamucil, 1 teaspoonful in water or orange juice immediately before eating.<sup>10</sup> Although this did not reduce the appetite sufficiently to cause a loss of weight, except occasionally, it did tide the patient over a period of refractiveness to the appetite-control drugs. After a period of two weeks the autonomic drugs could be resumed again, even in smaller amounts, with adequate control of appetite.

As experience was gained with the use of these drugs, it was found that only rarely was a rise in blood pressure or pulse rate seen. It is thus obvious why opinion on the value of these drugs varies so much, and why statistical analysis does not give an accurate picture. Each patient requires an individual dosage of each drug, and also requires an increase in dosage at a different rate. Some psychotherapy is also required in the case of each patient, sometimes during the treatment, and certainly after the treatment is discontinued. New eating habits must be established if a patient is not to regain his lost weight. All the female patients require some form of diuretic therapy during and often following the menstrual period. All the patients develop a refractoriness to the therapy, and therefore require a short period of rest. We have used the gel treatment in this interval. This same substance is usually required to be given for some period after satisfactory weight loss has

been reached, and until new eating habits have been thoroughly established. If this does not occur, the whole treatment has been wasted. Because of the relaxing effect of the drugs on intestinal musculature, constipation usually resulted and a mild laxative was advised.

The patient must be put on vitamin-mineral supplements as soon as therapy is started, because his dietary intake will often be erratic. In practice, the patient is put on at least one potent panvitamin capsule, along with two ferrous sulfate tablets in 3 to 5 grain dosage. It was found that these preparations are best given at night, so as not to confuse the patient.

Occasional reactions may occur, including headache, restlessness, insomnia, irritability, palpitation, and a disturbance of the bowel habit. However, it is necessary to state that these reactions are exceedingly rare, and are merely mentioned to call attention to their rarity.

Exercise is of benefit in the management of the obese patient. Exercise alone is usually not sufficient to cause an adequate loss of weight, and is a much harder way of reducing than by limitation of food intake through appetite depression.<sup>11</sup>

## RUSSIAN MEDICAL LITERATURE

Since the intimate association of the United States with Russia during World War II, anything pertaining to that great nation is of interest to the citizens of our country. Although modern medicine has been well established in Russia, we know little of its physicians or the work which they are carrying on. Information on these medical matters is offered to the physicians of this country through the bimonthly *American Review of Soviet Medicine*, published in New York. The contents of this journal comprise abstracts and reviews of Russian books and medical journals which aim to give English translations of their essential features. The

published numbers include papers on some conditions familiar to practitioners of our country, as well as interesting descriptions of diseases with which we have little familiarity, all of which offers valuable information.

The editor, Dr. Henry E. Sigerist, solicits the services of anyone familiar with the Russian language who is willing to serve in translating important medical publications for inclusion in this journal.

This will be worth-while service capable of benefiting any physician who has access to this journal.—*Northwest Medicine*, July, 1944

# THE ROLE OF DEVELOPMENTAL DIAGNOSIS IN CLINICAL MEDICINE

ARNOLD GESELL, M D , New Haven, Connecticut

**D**EVELOPMENT as well as disease falls within the scope of clinical medicine. For this reason the more advanced hospitals of the postwar world will be equipped with facilities for the diagnosis of the developmental status of infants and young children. With such facilities, we can come nearer doing justice to that large group of infants who because of intrinsic or acquired impediments, are unable to develop normally. This includes a vast array of conditions: simple amentias, aplasias, and malformations, degenerative processes, birth injuries and other traumas, toxemia, infections and toxic lesions, endocrine dysfunctions, sensorimotor handicaps, and severe environmental shocks and stresses.

## Behavior Patterns Are Symptoms

A developmental diagnosis is a diagnosis of the maturity of a growing organism. What is the most important symptom of maturity? Behavior. A man may be as old as his arteries, a baby is as old as his behavior. There is no more fundamental, no more comprehensive, no more significant criterion of developmental maturity. Height and weight tell us something. Metabolism ratings, x-ray photographs and biochemical determinations tell us this and that, but nothing sums up the developmental status of a child so completely as the behavior picture, because the behavior picture is a faithful image of the integrity and the organization of the child's nervous system. Of all his organ systems, the central nervous system is supreme. It determines his capacity to adapt to the world in which he lives.

The status of this nervous system should be brought more systematically within the scope of clinical pediatrics. Pediatrics is a form of general medicine. As such, it is concerned with all the life functions of the organism, including the basic function of development. And development can be fully appraised only in terms of the central nervous system and its outward tokens.

What are these outward tokens? They are patterns of behavior. As a technique, developmental diagnosis is a clinical developmental neurology which elicits patterns of behavior.

The ordinary procedures of clinical neurology are best adapted to frank neuropathologic conditions, but they are not very serviceable for observing the neuromotor system of an infant or

young child, and for discovering the early indications of developmental defects and deviations. We need a technique which will not arouse the protests and resistances of the infant, but which will invite him to display spontaneously and naturally the basic condition of his behavior equipment, namely, his neuromotor system.

## Diagnostic Procedures

Now, this is the logic which is behind the system of developmental diagnosis which we have organized in our Clinic at Yale University. The methodology is simple. The materials are simple (Fig. 1). We believe that in this very simplicity lies the usefulness of the technique. We use no artificial devices which are likely to disturb the equanimity of the infant. On the contrary, we take pains to preserve his contentment, to make him feel at home, to encourage his reactivity to the examination situation.

If he is a young infant, we begin our observations by simply placing him on his back. He inevitably rewards us with a behavior pattern. He assumes a postural attitude which may or may not be characteristic of his chronologic age. We observe his natural, spontaneous postural behavior. What postural attitudes do his eyes assume? What does he do with his head? His hands? His arms? His legs? Does he follow a ring dangled before him? Can he move his head to the midline? Up to the age of 12 weeks, if he is normal, he characteristically displays a tonic neck reflex attitude. Should he display this attitude at a more advanced age—say at 40 weeks—we would, in this one observation, have a neuromotor symptom which has great importance from the standpoint of diagnosis and prognosis. In the short space of fifteen minutes we can observe a wide array of behaviors—motor, adaptive, language, and personal social patterns of behavior.

When the infant is posturally mature enough, he can be placed in a supportive chair confronting a table top which spans the crib (Fig. 2). On this table-top we place test objects in accordance with standardized procedures which evoke behavior responses that can be appraised in terms of clinical norms. The test object may be a cube, an enamel cup, a ring with a string attached, or a tiny pellet.

## Diagnostic Appraisal

We are not interested in success and failure as such in these test situations. We are interested in

FIG. 1. Developmental test materials.

the shape of the patterns which are evoked. We wish to know how these shapes conform to normal traits, and whether the observed behavior pattern fits into a developmental gradient. Every pattern is an index of a degree and a kind of maturity. An accurate diagnosis depends upon a judicious weighing of the numerous indicators of maturity which the infant spreads before us with prodigality as he addresses himself to the test objects.

Inasmuch as we are not interested in plus and minus ratings or success and failure scores, it is needless to say that we have no interest in calculating an arithmetic intelligence quotient. Infant

I.Q.'s are all but meaningless. They have the appearance of quantitative precision because they are derived by dividing a numerator by a denominator. But an uninterpreted I.Q. may be extremely misleading because of defects in the examiner, in the infant, in the examination procedure, and in the measuring scale applied. The I.Q. has been seriously misused in the classification of children of school age. The dangers of misuse in the first two years of life are so grave that the pediatrician will be well advised to beware of the simplification of any I.Q.

The objective of developmental diagnosis is the appraisal and interpretation of developmental assets and liabilities. Such interpretations can neither be summed up by nor posited on a numerical I.Q. Developmental diagnosis, therefore, should not be confused with a psychometric type of mental testing. From the standpoint of clinical medicine, development is a complex process which requires critical and considered analysis which takes into account all the attendant and historical medical factors. This is equally true whether the diagnosis is concerned with relatively normal children or seriously defective children or problematic children with complex conditions that demand refined differential diagnosis. Normality presents its own distinctive clinical problems.

In this biologic sense, development as well as disease falls within the scope of clinical medicine. This is a fundamental thesis which applies with peculiar force to pediatrics. The pediatrician is charged with the responsibility of promoting optimal child development and recognizing all the factors which interfere with such develop-

FIG. 2. An infant behavior test. A ring and string have been placed on the table top of the clinical crib to elicit adaptive behavior.

FIG 3 A developmental examination of a preschool child, showing one-way vision screen arrangement

ment. He places his first and foremost reliance upon nutrition. But this is only the beginning of a broader supervision which includes the total economy of growth and development. Pediatrics, we repeat, is a form of general medicine, and as such it is also psychosomatic medicine.

Now how can this new type of developmental diagnosis, this type of supervisory medicine and pediatrics, be put into operation? Like any other branch of clinical medicine, developmental diagnosis may be undertaken at various levels of skill and thoroughness. As a clinical specialty, developmental pediatrics demands at least a year

internship in

At a more ordinary level of application, developmental diagnosis depends chiefly upon a working familiarity with a few simple test procedures, plus natural aptitude and clinical insight into the symptomatology of behavior traits. With a little systematic interest, technical skill is readily acquired.

There are two major fields of application: (1) routine, and (2) consultative.

#### Routine Applications

The clinical protection of child-development demands routine regard for behavior symptoms

in private practice, in infant welfare examinations, in child-health supervision, in children's hospitals, and in all child care agencies charged with administrative responsibilities. At the lowest minimum, there should be a behavior inventory which will disclose the most serious developmental defects and deviations. Such an inventory will not have diagnostic conclusiveness, but it will have a prediagnostic screening value, and may become a useful part of the child's record. A screening type of behavior survey by inventory and developmental examination is destined to become a standard feature of child protection, both in private practice and in child-welfare administration. How else can we do justice to children who are not developing normally, who are temporarily wards of hospitals or permanent wards of the community?

#### Referrals for Intensive Diagnosis

Every sizable community already needs specialized facilities for the diagnostic study of the more complex forms of maldevelopment, the outpatient division of a hospital is the logical place for such facilities. The developmental appraisal should be not a by-product but a separate undertaking, using all available evidence, but directed to a careful analysis of behavior

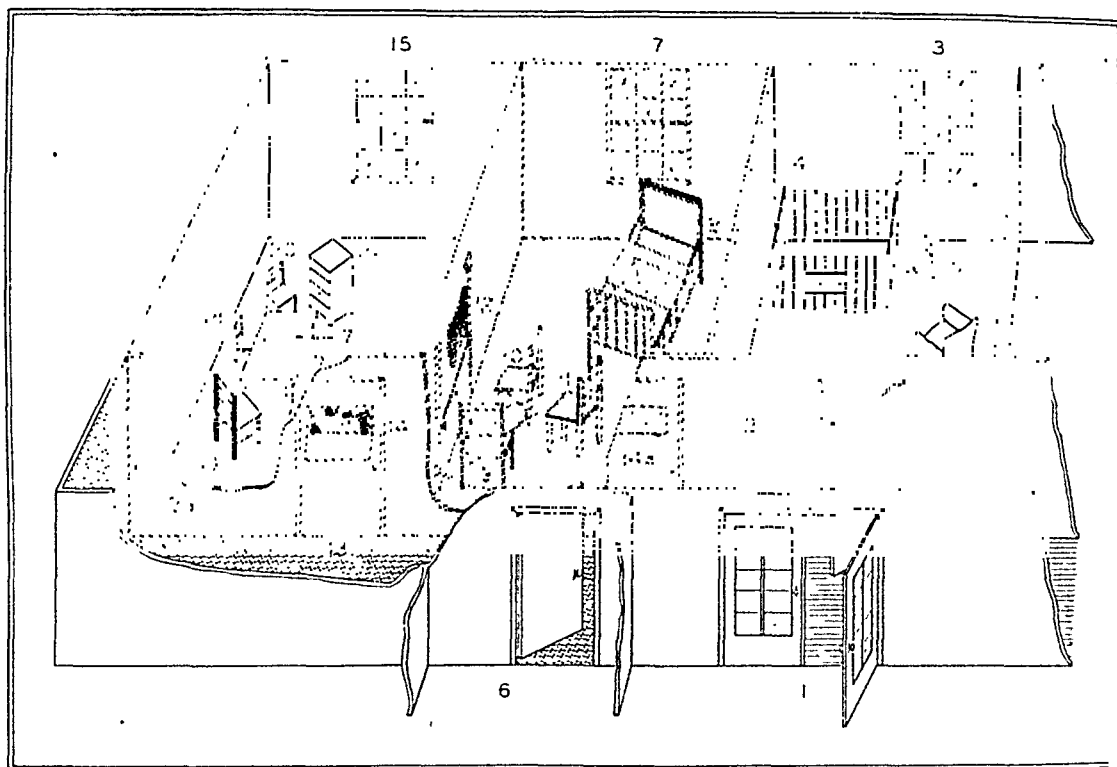

FIG. 4. A suite for the developmental examination of infants and preschool children. A function description of the arrangements follows:

Assume a child of preschool age, accompanied by a nurse or mother. The child enters at (1), pass through the hallway (2) which connects with the reception room (3) and also with the bathroom at (6). The reception room is furnished with adult chairs and a play pen (4) and child's chair (5). The observation room (7) has been partially darkened by drawing the shade at the window. The recorder takes static in the chair equipped with writing arm (9). Observers can be seated nearby, behind the one-way-vision screen window (12) which communicates with the examination room (15), entered by the door at (13) also equipped with one-way-vision window (14). The examination room is equipped with an examination table (16) showing the picture book (17) and child's chair (18) in position. The mother sits at the right (19), the examiner at the left (20), with direct access to the examining cabinet (21).

If the child is of infant age, the same facilities are used in a slightly different manner. Room 7 becomes the examining room and room 15 the observer's and recorder's room. The one-way-vision screen window in the communicating door (12) operates equally well in the reverse direction. The examining crib is moved to a favorable position.

status. This means a separate locus, special equipment, and trained personnel on a par with electroencephalography, ophthalmology, radiology, or any other diagnostic department. The arrangements must be planned to insure optimal responses of the infant and the young child. Such arrangements are indispensable for the systematic follow-up supervision and parent guidance so seriously needed in all cases of maldevelopment.

A permanent diagnostic department will also become a natural center for demonstration, teaching, and intern training. It alone can establish the high standards of diagnosis which are necessary as a rampart against a superficial form of I. Q. psychology. The diagnosis of development is psychosomatic medicine. So long

as pediatrics remains a generalized form of medicine, it must bring the central nervous system squarely within its scope. It can do so only through a system of developmental diagnosis which appraises the maturity and the organization of the infant's behavior.

That is the role of developmental diagnosis in clinical medicine.

### Supplement

Slides and cinema were shown to illustrate the methods of developmental diagnosis, particularly as applied to infants. A film entitled "Developmental Neurology and Developmental Diagnosis" was demonstrated. This film depicts normal neuromotor patterns at 4, 16, 28, 40, and 52 weeks. Abnormal neuromotor patterns are comparatively delineated as follows: spastic paraplegia (age, 32 weeks); minima

cerebral injury (age 36 weeks), mild athetosis (age, 40 weeks), minimal cerebral injury (age, 44 weeks), minimal cerebral injury (age, 48 weeks), mild athetosis (age, 52 weeks) severe athetosis (age, 56 weeks), minimal cerebral injury (age 56 weeks), cerebellar aplasia (age, 2 years), mild athetosis (age, 2½ years)

A developmental examination is a practical method of appraising the competence of the neuromotor system. The film shows a few selected normal neuromotor patterns at salient ages to indicate their progression and development. Series of selected clinical cases delineate varying degrees of neurologic impairment. Although gross defects are represented in the film, the emphasis is on manifestations of minimal cerebral injury which often lead to an erroneous diagnosis of mental defect which can be best detected and interpreted by methods of developmental diagnosis.

The practicability of incorporating these methods into hospital organization is suggested.

The accompanying illustrations indicate the materials, the examination arrangement, and diagnostic procedures used. Figure 1 shows the test materials used in the behavior examination. Figure 2 shows an infant behavior test to elicit adaptive behavior. Figure 3 illustrates the developmental examination of preschool child with an arrangement for one way vision observation. Figure 4 diagrams a suite for the developmental examination of infants and preschool children.

The diagnostic procedures and clinical applications are described in detail in Gesell, Arnold, and Amatruda Catherine S. *Developmental Diagnosis Normal and Abnormal Child Development*. New York, Paul B Hoeber Inc, 1941 page 447.

## Discussion

Dr Harry Bakwin, New York City—For many years now the principal function of the pediatrician in America has been the care of the well child. Trying to keep children well and detecting minor deviations from optimal health have not been simple tasks. Perhaps the most difficult part of the job has been the differentiation between what is normal and what is abnormal.

As the function of the pediatrician broadens, as pediatrics takes upon itself the task of guiding the child in his mental, emotional, and motor attributes as well as in his physical traits, there arises a corresponding need for information in these fields. We must know more than the few crude facts about when the baby sits without support, when he walks alone when he says mama and papa etc. If we are to make judgments about the psychologic status of children we shall not only have to acquire a fresh viewpoint toward child care but we shall need as well an entirely new set of developmental criteria for judging the integrity of the nervous system. It is true that pediatricians have observed many of the things that Dr Gesell and his group have pointed out, but we have not been conscious of their significance and we have not been able to relate them accurately.

Take, for example, Dr Gesell's observations on

the behavior of the 4 week-old child. We have not been in the habit of noting the visual activity at this age, how the baby begins to fix on objects and show some interest in them, how his general body movements diminish momentarily when some interesting stimulus meets his eye. This is only one of innumerable observations which Dr Gesell has made and which has clinical value in assessing the mental and motor status of the infant.

In the observations on the behavior of children, some of which have been demonstrated to us today, a new and broader attitude toward the examination of children is implied. The pediatrician, no longer limiting his examination to the "physical examination," now has available to him a mass of data to which he may refer in order to assess certain aspects of the developmental status of his patient. And these data are as objective as clear cut as the findings with the stethoscope, the reflex hammer, and the percussion finger.

Especially valuable are the studies of Dr Gesell and his group on the baby as a whole—the observation of all the activities of the baby over the entire twenty-four hour period. These observations on the self regulated baby are as revealing, in a way, as were the early studies of disease uninfluenced by therapy. You will recall that for many years—indeed, up to about 100 years ago—recovery from many diseases, for example, typhoid fever and pneumonia, was looked upon as the result of therapy and not as the natural course of the disease. In a similar way we, too, have tended to look upon the schedules which we more or less arbitrarily imposed on children as the proper ones. After all, children thrived on them, thanks to their adjustability and their ability to "take it." We failed to see that the optimal schedule is that which the developmental status imposes on the child, a fundamental concept for which pediatrics owes a great debt to Dr Gesell. Using the unfolding of the developmental process as the guiding principle determining the handling of the child, rather than a plan based on ancient ideas and carried on by tradition reinforced by false rationalization has revolutionized the whole attitude toward child care. It is hardly necessary to point out to this group that a complete change in pediatric

so much to foster overanxiety in the parents and revolt in the children has been replaced by a flexibility and an individual adaptability which we trust will lead to happier parenthood and happier childhood.

It is a pleasure to have this opportunity to pay tribute to Dr Gesell and his able group of coworkers for their fundamental contributions to the theory and practice of pediatrics. Dr Gesell has provided us with a set of principles which serve as the ground work on which our ideas of modern child care are built, he has presented data to prove his thesis, and, with infinite patience and extraordinary tenacity of purpose, he has accumulated a mass of data ready for clinical application.

Pediatric practice needs to catch up with Dr Gesell.

# NUTRITIONAL IMPROVEMENT OF CHILD MENTALITY

I. NEWTON KUGELMASS, M.D., Ph.D., Sc.D., LOUISE E. POUILL, Ph.D., and  
EMMA L. SAMUEL, M.A., New York City

MENTAL energy is a product of two factors—capacity and intensity; one is determined by heritage and maintained by essential nutrients, especially proteins, lipids, water, and anions, while the other factor depends on immediate availability of dextrose, oxygen, vitamins, and cations. Metabolic disorders affecting the capacity factor or brain structure tend to produce irreversible anatomic lesions, while nutritional disorders affecting cerebral function tend to produce reversible biochemical lesions. The role of some essential nutrients has been evaluated in the mental activity of experimental animals but the applicability of this knowledge to children is a moot question. Since multiple nutritional deficiency predominates, the pertinent problem is to determine the effect of malnutrition on retarding mental function. Despite the difficulty of evaluating the nutritional status of children at various ages and the task of excluding underlying diseases affecting mental growth, we have, nevertheless, been able to study the effects of nutritional improvement on child mentality in 182 children from 2 to 9 years of age, half of them institutionalized at the New York City Children's Hospital and the Fifth Avenue Hospital and the other half outpatients at the Heckscher Institute, Bailey Hall, and the senior author's office.

Group I included 41 mentally retarded and 50 normal children, malnourished at the time of the first mental test and well nourished at the time of the second test. Group II included 41 retarded and 50 normal children, well nourished at the time of the first test and still well nourished at the time of the second test. Each group was equated for chronologic age, I. Q., and interval between Kuhlmann-Binet or Stanford-Binet tests. The data in Tables 1, 2, and 3 reveal an average rise of 10 points for retarded and 18 points for normal children of Group I in contrast with an average of no change for the retarded and a  $-0.9$  change for the normal in Group II. The greater variability shown by higher standard deviation of I. Q. in Group I in comparison with Group II is probably due to the initial variations in nutrient deficiency and individual responses to nutritional therapy. The significance of this difference in I. Q. change in favor of the malnourished group is 2.43, indicating that chances are 99.2 in 100 that the difference is greater than zero.

There is a significant correlation between the age at the time of the first test and the I. Q. rise.

A correlation of  $-0.56$  is a clear indication that the younger the malnourished child when nutritional therapy is instituted, the greater the chance of improvement in mental function. Indeed, the sharp decline in average I. Q. rise for the malnourished group after the age of 4 years suggests that irreparable damage is to be expected in older children. Flexibility of I. Q. change during the first four years of life bespeaks reversibility in mental development, while relative constancy in I. Q. change in older children bespeaks irreversibility in mental development following prolonged malnutrition. The slightly positive correlation between the length of the interval and the I. Q. rise in the malnourished group as compared with the zero correlation of the well-nourished group suggests that as long as two years may be necessary to bring about the average gain in I. Q. following nutritional therapy.

## Summary

1. The effect of nutritional improvement on child mentality has been determined in 182 children, 2 to 9 years of age, half institutionalized and half outpatients, for a period of fourteen years.

2. The group of children malnourished at the time of the first mental test and well nourished at the time of the second test showed a rise of 10 points for the retarded and a rise of 18 points

FIG. 1. Effect of nutrition on mentality.

TABLE 1.—EFFECT OF NUTRITION ON MENTALITY

	Malnourished Groups				Normal	
	Range	41 Retarded	Average	Range	50	Average
Age	2-8 years	3 years 10 months		2-10 years		4 years 8 months
I. Q.	20-90	45		95-145		110
Interval	1-7 years	3 1/2 years		1-3 1/2 years		2 years
I. Q. change	-8 to +44	+10		-12 to +55		+18

	Well-Nourished Groups				Normal	
	Range	41 Retarded	Average	Range	50	Average
Age	2-8 years	4 years 10 months		2-10 years		5 years

TABLE 3.—I. Q. CHANGE/AGE IN MENTALLY DEFICIENT GROUP

Age	Malnourished—Average		Well Nourished—Average		Difference
	No. of Cases	I. Q. Change	No. of Cases	I. Q. Change	
2	11	+13	5	+2 4	+10 6
3	15	+14 4	7	+2 8	+17 2
4	8	+5 3	10	-1 8	+7 1
5	0		8	+1 6	
6	5	+1 6	9	-0 7	+2 3
7	2	+0 5	2	+1 0	-0 5

I. Q. CHANGE/INTERVAL IN MENTALLY DEFICIENT GROUP

Interval	No. of Cases	Average I. Q. Change	Range
6 months to 11 months	11	+5 6	-4 to +26
12 months to 18 months	12	+6 8	0 to +28
19 months to 25 months	7	+10 7	-2 to +20
26 months to 32 months	6	+11 3	0 to +23
33 months to 5 years	5	+0 6	-0 to +9

for the mentally normal in contrast with an average change of zero for the group well nourished at the time of the first test and still well nourished at the time of the second test.

3. The younger the malnourished child when nutritional therapy is instituted the greater the chance of improvement in mental function, since the I. Q. rise is insignificant after 4 years of age.

## NATIONAL COMMITTEE ON ALCOHOL ORGANIZED

The organization of a National Committee for Education on Alcoholism, Inc., was announced October 2. Offices will be at 2 East 103rd Street, New York. Elvin M. Jellinek, Sc.D., director of

the Yale School of Alcohol Studies, New Haven, Connecticut, is chairman of the board of the new committee and Mrs. Marty Mann is executive director.—J.A.M.A., Oct. 21, 1944

# Therapeutics

## CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the January 1 issue and will concern "Uses and Abuses of Quinidine."

### Evaluation of Local Antisepsis

DR. MCKEEN CATTELL: Today we will attempt to evaluate antiseptics, with special reference to the problem of securing local antiseptic action by the application of drugs or other treatment directly to the skin and other tissues. The extent to which such antisepsis may be attained as well as the relative effectiveness of different procedures are important but difficult questions.

The discussion will be opened by Dr. Modell.

DR. WALTER MODELL: Many important advances which have been made in medicine have followed the introduction of antibacterial measures. Thus the pasteurization of milk, the treatment of drinking water, the sterilization of contaminated excreta, and the fumigation of ship-holds have saved countless millions of lives and have probably prevented disease in many more millions. In a lesser way statistically, but just as dramatically, the introduction of the aseptic technic in surgery, of the sterile glove, the sterile gown and drapes, and the sterile scalpel have changed the face of surgery. All these very effective measures kill bacteria before they reach the human host.

However, the destruction of bacteria by means of chemical agents after they reach the human host presents special problems, many of which have, up to only recently, completely defied solution. The systemic introduction of chemicals to destroy bacteria which have invaded the blood stream or the organs of the body met with practically no success until the development of the sulfonamides and penicillin. We have grown accustomed to failure in the quest for systemic antibacterial agents.

The prospects had always looked better for the surfaces of the body, the skin and the mucous membranes. Materials used for these surfaces are referred to as local antiseptics or disinfectants. There is no sharp distinction between them, although the term "disinfectant" is more frequently employed to convey the notion of complete destruction of the organisms, while "antiseptic" is more often applied to mere reduction of growth and multiplication of bacteria.

In relation to the compounds used for these purposes, the difference is often only a matter of concentration.

Faith in the efficacy of locally applied antiseptics or disinfectants is widespread. It seems like a simple step from the demonstration of powerful destructive action on bacteria in a test tube to a similar action on such bacteria invading the surface of the mucous membrane or the skin. However, the problems are rendered very difficult by the complexity of the structure of the skin and mucous membranes and the conditions attending the invasion of these tissues.

There is now ample proof that inferences drawn from test-tube experiments may not apply to skin and mucous-membrane disinfection. While there is no doubt that drops of silver nitrate solution in the eye prevent gonorrheal ophthalmia in the newborn, and a few other similar examples might be cited, there is indeed a question whether the application of disinfectant agents to the skin or mucous membrane does not often do more harm than good. At any rate, the view that the use of drugs by local application for the destruction of bacteria may give us a false sense of security deserves abundant consideration.

The list of substances which have antiseptic properties outside the body is long. In *New and Nonofficial Remedies* about twice as many pages are devoted to the listing of the anti-infective substances as to any other group of drugs. Attempts to attack bacteria by different mechanisms have led to a multitude of different types of agents, such as acids, alkalis, oxidizing agents, halides, freely ionized metals, poorly ionized metals, benzols, alcohol, formaldehyde, and the dyestuffs. Our discussion will concern itself chiefly with those which are for the most part nonselective, and destroy protoplasm pretty generally. There are, of course, the special problems of penicillin and the sulfonamides, which are not general protoplasmic poisons, whose actions are more specific, and, while they are employed for local application, apparently

with some success, they are not commonly classed among local antiseptics and disinfectants

Let me first point out how some of these disinfectants and antiseptics act and the factors which undermine the test-tube efficacy of these agents when they are applied directly to the skin and mucous membranes

Acids and alkalis change the pH of the medium in which the bacteria live, some dyes react with acid or basic radicals of the bacterial protoplasm, mercuric chloride precipitates bacterial protein, while the organic mercurials are thought to combine with sulphydryl groups of metabolites and phenols to combine with amino groups in the bacterial protein

Many factors modify the antiseptic power of these agents. Time is an important element. No antiseptic acts instantaneously, but the speed of action varies. Thus, whereas the phenol coefficient of mercuric chloride is only 13.5 in five minutes, in ten minutes it rises to 175 and in thirty minutes to 550. The significance of the time element is increased when dilute solutions are used, yet these are the only kind of solutions which may be used in therapy. Many factors in local application conspire to limit the effective time of exposure to any particular solution, such as evaporation, absorption, chemical combinations, and dilution. The temperature at which the antiseptics act on bacteria is also important. In general the effectiveness increases with temperature in the same type of curve as most chemical reactions. While it is possible outside the body to maintain the optimal temperature, in therapy, obviously, no such control is feasible. Specific concentrations of antiseptics have been found to be the most effective against bacteria, or to give the optimum relation between toxicity for the bacteria and for the host. Yet the same factors which make the control of the time of exposure to bacteria impractical also seriously interfere with the maintenance of optimal concentrations. Thus, 70 per cent alcohol by weight is said to be a critical concentration. Yet a moment after application to the body this concentration is quickly reduced.

Surface-tension characteristics of antiseptics are important in therapy. Lowering surface tension by adding reductants often increases the potency of a drug. This is said to be caused by favoring permeation or penetration, accelerating osmosis and diffusion, and making the surface reaction between the bacteria and the antiseptic a more intimate one, therefore, lowering the surface tension produces the same effect as increasing concentration. On the other hand, it should be remembered that the interfacial tension between air and liquid, as surface tension is usually measured, may give no accurate informa-

tion concerning the tension at the interface between the antiseptic and the bacterium.

The ability of antiseptics to penetrate varies considerably. Antiseptics in the colloidal state have little penetrating power, while the same substances in true solution have, in general, considerably more. Antiseptics which coagulate or precipitate protein penetrate more poorly than those which do not, therefore, the phenolic antiseptics usually penetrate more efficiently than mercuric chloride. Penetration *in vivo* is always an important problem, since the multicellular membrane of the skin and organs presents a formidable barrier to all antiseptics. The presence of protein in the medium seriously embarrasses antiseptic action. Protein affords the bacteria mechanical and chemical protection. It prevents penetration, it reacts with the antiseptic to render it inert, insoluble, or less toxic. Particulate matter may adsorb some of the antiseptic. While this effect is universal, some, such as the chlorine compounds and potassium permanganate, are far more seriously impaired by the presence of organic matter than others, such as the benzol derivatives. It hardly needs mention that organic matter cannot be avoided or in any way limited in therapy with antiseptics, and as a matter of fact, the situation which calls for the use of antiseptics is often that which is accompanied by a free flow of serum or pus.

In evaluating these agents several tests are applied which attempt to take these limiting factors into account. The phenol coefficient, which when first conceived, tested only the potency of an agent against the Hopkins strain of *Bacillus typhosus* under standard conditions of temperature and time, has been expanded and modified to test as well a variety of organisms, the effect of organic matter, and penetration of a gel. In addition, the effect of these agents on suspensions of leukocytes or embryonal cells is also tested to obtain a ratio of toxicity between animal and bacterial cells.

All these tests applied to a drug appear to give a well rounded answer concerning the relative effectiveness of an antiseptic. Yet the expected efficacy is usually not realized when the antiseptics are given actual therapeutic trial. Some reasons for this failure have already been pointed out. Most antiseptics penetrate tissues poorly, yet most so-called surface infections are at least several cell layers deep. The cell membrane is a greater barrier to penetration than the agar gel which is usually used to test penetrability *in vitro*. A study by Nungester and Kempf has a bearing on this point. They swabbed the tails of mice with cultures of streptococci. Then they dangled the tails in baths of one of several anti-

septics to be tested. Finally the tails were amputated and implanted into the peritoneal cavities of the mice. Practically all died of peritonitis. The inoculation with the bacteria was on the surface of the skin, and surely there is no more effective way of applying antiseptic than dipping. Yet, since some bacteria must have penetrated several layers of skin, this presumably effective treatment was not effectual. This difficulty in penetration also accounts for the serious problem encountered in sterilizing catgut by any method other than heat.

The shape of the infected area is important. A simple experiment demonstrates this. It is easy to sterilize the walls of an ordinary test tube with any ordinary potent antiseptic; yet if the walls of the test tube are drawn out into many thin filaments, making a multitude of crevices, it becomes exceedingly difficult to sterilize the tube with the same chemicals. This type of wound-model indicates why the irregularities and crevices of infected wounds seriously retard the action of antiseptics.

Antiseptics may also destroy some of the body's defenses against infection. Thus Fleming has shown that when lysozyme, one of the natural antibacterial defenses, is mixed with solutions of chlorine antiseptics, the power of both is reduced. The result of such a combination therefore favors bacterial development. Fleming maintains that often the concentration of an antiseptic is quickly lowered after application to a level below that which is antibacterial but which remains for some time antagonistic to the natural defenses of the body.

The cells of the skin and organs and the leukocytes may also be killed by effective concentrations of antiseptics. Very few antiseptics indeed have a truly favorable therapeutic index, *in vitro*, killing or inhibiting bacteria at significantly lower concentrations than they do leukocytes. Thus most of them also kill some cells, irritate others, stimulate the flow of serum, and produce the best possible medium for the growth and multiplication of the bacteria which survive the initial antiseptic blow. There is evidence collected during the last war which showed that after contaminated wounds were débrided, irrigation with sterile saline produced cleaner wounds, and wounds which healed more quickly than those treated with any of a number of antiseptics. Indeed, impression cultures showed that the bacterial flora was most luxuriant in those wounds treated with antiseptics, while it was very sparse, by comparison, in those merely irrigated with sterile saline.

All of the factors mentioned conspire to make what looks like an effective antiseptic not only useless but sometimes also harmful.

I would like to end with a quotation from Alexander Fleming written some twenty-five years ago. He referred only to surgery, but the same advice applies to all medical practice in which antiseptics are used. He said that the evidence "would seem to show that the antiseptic plays no part in the primary treatment of wounds. If this is so, then there is a very great disadvantage in the use of an antiseptic from the surgeon's point of view. It is very difficult for the surgeon not to be deluded into the belief that he has in the antiseptic a second string to his bow, and consequently it will tend to make him less careful in his surgical treatment of the wound. If he knows that he has nothing to fall back on, then, even with the most conscientious individuals, the surgery would improve. Because of this alone it would be well if the treatment of the wound with antiseptics in the early stage were abandoned and the surgeon relied on his skill alone. All the great successes of primary wound treatment have been due to efficient surgery, and it seems a pity that the surgeon wishes to share his glory with a chemical antiseptic of more doubtful utility."

DR. CATTELL: Dr. Modell has made some challenging statements. I don't know whether he is going to be allowed to get away with all of them. We have present men working in the fields of dermatology, surgery, urology, and medicine, and we would like to hear from them in relation to this problem.

DR. C. H. WHEELER: I wonder if we might ask Dr. Modell to define the problem a little more closely.

DR. MODELL: I question whether any useful purpose is served in rubbing the skin with a little alcohol before introducing the needle through it for a hypodermic injection, whether there is any value in swabbing an infected throat with an antiseptic, whether there is any use in irrigating an infected bladder with such agents, or the eye, or the vagina, or a wound. I think that these are for the most part useless gestures, sometimes detrimental, and that reliance on these attractive practices leads one away from better drugs and better technics.

DR. C. GARDNER CHILD: Probably no single technical subject in surgery has been the object of more attention than has this one. In attempting to further good surgical technic innumerable efforts have been made to discover some agent which would sterilize the skin through which an incision was to be made. I think that in general the remarks already made hold true. It has certainly been discouraging to discover that each of the chemical agents, as it has been placed in use, has proved to be ineffective or to do more harm than good. In a recent report the

author found his results as good, in fact better than previously, when the only agent he used for preparing the skin was a bland white soap and water

At the present time the Department of Surgery uses the following method of skin preparation. First, fat and grease are removed with benzene, followed by alcohol and ether. The skin is then painted twice with 3.5 per cent iodine, which in turn is removed with alcohol. Some degree of superficial sterilization of the skin is probably accomplished by this method, but certainly it does not extend to the deeper layers, into the hair follicles or skin gland systems.

Traumatic wounds constitute a much larger problem. Here mechanical cleansing with copious amounts of saline and thorough débridement are the only methods employed in converting a contaminated wound into a clean wound.

From the surgical point of view I would agree almost entirely with what has been said this afternoon, namely, that the mechanical cleansing of the skin and wounds is about all that is effective. The use of various chemical antiseptics accomplishes little and often is harmful.

DR JOHN M. McLEAN: Do you use any soap on the skin?

DR CHILD: Yes.

DR MODELL: In connection with skin preparations, Price has shown that after scrubbing the hands with soap and water for about ten minutes about 100,000 bacteria can still be recovered from the wash water. After sterile gloves have been on, for two or two and a half hours during an operation, the bacterial population may again be as high as it was before the scrubbing.

DR BERNARD MAISEL: Price also reported that the use of alcohol and soap facilitated the lowering of the bacterial flora of the hand.

DR MODELL: But no measures make the hands absolutely sterile. Price has shown that antiseptics may fix bacteria to the skin of the hands but neither kill nor remove them. They may still be viable.

DR HARRY GOLD: Do you imply that alcohol used with the soap in scrubbing exerts an antiseptic action?

DR MAISEL: I think that was a statement of Price in his report.

DR GOLD: Isn't there something strange about that, since other reports show that it may take as long as sixty minutes for alcohol to kill the staphylococcus?

DR MODELL: Price found that a specific strength of alcohol, namely, 70 per cent by weight, made an effective antibacterial washing solution. This concentration takes much care in preparation and is easily disturbed. For

example, it is quickly changed during the course of its use as a wash. The slightest deviation from 70 per cent by weight—not by volume—makes it an ineffectual wash.

DR GOLD: I would like to ask why we continue at the New York Hospital the time-honored mixture of alcohol and iodine in preparing the skin for operation? Is that just tradition?

DR CHILD: It probably is mostly a matter of tradition.

DR CATTELL: Is not the color helpful?

DR CHILD: We take the color off.

DR CATTELL: You do finally, but it tells you where you have been.

Perhaps we will take up some of the other aspects, and from here go on to the dermatologist, Dr Sulzberger.

DR M. B. SULZBERGER: In his remarks Dr Modell has defined "antiseptic" in a somewhat restricted sense and has also deliberately excluded from his discussion a number of recognized bactericidal or bacteriostatic agents such as sulfonamides, penicillin, etc.

For the purposes of my own comments I shall define an "antiseptic" in the usual or classic way, i.e., as given in standard medical dictionaries. The definition of an antiseptic, then, usually reads something like this: "An agent which prevents the action of germs which produce fermentation, putrefaction, or disease." I believe it must be granted that under this definition many agents used on the skin's surface or on wounds or skin infections act as antiseptics.

I say this despite my essential agreement with the facts which Dr Modell has so well set forth, all showing that no known form of external application is capable of effecting complete or perfect sterilization of the skin's surface without damage to the skin itself. We have found that neither living skin in its natural position nor excised skin tissue can be completely freed of the presence of living micro-organisms by any form of application, which does not destroy or seriously damage the living cutaneous tissue. When Dr Rudolph Hecht and I made "skin antigen" for sensitization experiments and skin tests, we used many different bactericidal and bacteriostatic solutions including iodine, mercurials, and sulfonamides in our attempts to sterilize the excised skin and still preserve its characteristic specificity. We were unsuccessful, and bacteria remained viable in the excised pieces.

This fact is even more apparent when trying to sterilize the living skin on the body. Older studies and the more modern washing experiments of Price, cited by Dr Modell, the experiments of Pillsbury, Livingood, Nichols, and Shaffer with wash waters, with other agents, and with sulfonamides, all prove this fact. We possess no measure

or method which will destroy all the micro-organisms (many of which live and propagate within the horny layer and within the skin crypts and openings of the follicles and glands of the skin) without damaging the living skin cells. This is the basis for Dr. Modell's important conclusion that there has been a rather general tendency to lean more heavily on external antisepsis than the facts appear to warrant.

Nevertheless it would, I believe, be erroneous to conclude that local antisepsis is of no value whatsoever. Take for instance the soap-and-water-washing experiments of Price and the sulfonamide studies of Pillsbury and coworkers. These procedures produced a very considerable reduction in the number of bacteria on and in the skin. Dr. Modell, do you happen to recall the degree of reductions in numbers in Price's washings?

DR. MODELL: After ten minutes of scrubbing, the numbers were reduced from about ten million bacteria to about one hundred thousand in the last wash water.

DR. SULZBERGER: Such distinct reductions in numbers of micro-organisms must be considered as a demonstration of the possible antiseptic effect of soap and water and of other agencies applied—for, granted a certain degree of natural protective capacity on the part of the tissues, the actual number of potentially pathogenic bacteria is a significant factor in overcoming tissue resistance—and reduction in their numbers may well prevent the action of germs producing disease. The damaging effect upon micro-organisms, the bacteriostatic effect or inhibition of generation and of multiplication, and the fixation or mechanical removal which can be accomplished either by chemotherapeutic agents, by solvents and precipitants and fixatives (alcohol, etc.), by washings, or by many of the other external measures generally employed, all are worthy of consideration as practical antiseptic measures—provided one condition is fulfilled. This condition is that the measures used to remove, fix, or damage the micro-organisms have the proper *therapeutic index*, i.e., that they accomplish their effects in regard to the micro-organisms without producing too much damage to the skin tissue. This is of the very greatest importance in cutaneous antisepsis in relation to both prophylaxis and treatment of infection, for even slight degrees of skin damage may materially interfere with the usually adequate and remarkably efficient natural bactericidal and protective powers of the skin and its secretions. The *vis medicatrix naturae* of the normal skin is the most important factor in the prevention of cutaneous infections. We must preserve these protective powers at all costs. Any measure which radically disturbs or

destroys the normal "acid mantle" or the skin's electrophysical barriers or the bacteriostatic properties of sweat or which in any other way interferes with the truly remarkable natural protective mechanisms is likely to do more harm than good, regardless of its intrinsic or in vitro bactericidal or antimycotic activity.

This is one reason why there is so little relationship between the antibacterial or antimycotic activity which an agent may evidence in the laboratory, and the effects achieved by that agent when used on the skin. Another very striking reason for the almost constant discrepancies between *in vitro* effects and clinical therapeutic effects is that the actual mechanisms by which agents applied to the skin cure or prevent microbial disease often have no relationship whatsoever to bactericidal or fungicidal mechanisms as manifested in vitro.

Among the most important mechanisms operative in curing or preventing infection is that of removal of large numbers of pathogens from the skin's surface. One way in which this is accomplished is by dissolving, emulsifying, and washing off grease and horny material and sweat and dirt (the skin's "soil") together with the micro-organisms which are intimately incorporated in this soil. Another and most efficient way of preventing micro-organisms from producing disease is by helping the skin itself cast them out. This can be done through the application of agents promoting desquamation. It appears to me probable that many of the medicaments we use in treating surface infections (and particularly in treating or preventing fungous infections) effect their benefits by promoting more rapid desquamation and thereby aiding in the removal of the pathogenic agents. This mechanism may well be the *modus operandi* of such common "antiseptics" as salicylic acid, benzoic acid, resorcin, mercurials, sulfur, tincture of iodine, etc.

Another manner in which infecting agents are removed is through the measures employed to soften and evacuate abscesses, or to remove crusts or secretions, etc., in which micro-organisms may be present or may thrive. Thus, compresses, wet dressings, keratolytic or softening ointments and plasters, soap and water, etc., all become "antiseptics."

Still another form of cutaneous antisepsis acts through mobilization and concentration of the natural protective agents of the circulatory and tissue fluids, bringing the phagocytic cells, the antibodies, and other anti-infectious agents to the site. This action is inherent in hot poultices, in "counterirritants," etc.

A more subtle form of antisepsis is effected by measures which preserve or restore the nor-

mal hydrogen ion concentrations of the skin's surface. In most areas the normal skin's surface is distinctly acid, having a pH between 3.5 and 4.5. It is obvious that this acidity is protective, since it tends to damage and impede pathogenic micro-organisms. As soon as there is the slightest abrasion, interruption of continuity, or inflammation, the pH tends to increase, and many skin lesions have a pH as high as 7.0, 7.5, or 8.0. Medicaments with acidifying and buffer effects, such as Burrow's solution, combinations of organic acids and their salts (lactic acid, propionic acid, undecylenic acid, succinic acid, etc.) probably help to restore the normal degree of acidity and thus help to counteract infection.

It will be apparent that these few measures I have been able to list all act by aiding and sometimes by intensifying, the natural antimicrobial protective mechanisms of the skin. These effects can therefore never be observed or studied through *in vitro* experiments. They are, nevertheless, antiseptic effects—not, perhaps by Dr. Modell's definition but certainly by the classic definition of "agents which prevent the action of germs which produce disease."

In addition to these measures there are conditions under which the intrinsic *in vitro* bactericidal or bacteriostatic or fungicidal or -static effects of medicaments prove useful. Thus, for example, in treating impetigo contagiosa the cure may be accomplished by aiding the natural resistance by merely scrubbing off the crusts and applying softening and occlusive measures, such as the application of an inactive grease like petrolatum. However, it is undeniable that the *autoinoculation of new sites* tends to be inhibited if a mercurial or sulfonamide or other such antiseptic is incorporated in the ointment or other topical therapeutic agent which is spread over the skin's surface and stands ready to catch the micro-organisms which are being disseminated from the sites of the original lesions.

In this manner the iodine or mercurial painted on a belly may serve to good purpose, not by destroying all the micro-organisms already present in those skin areas, but perhaps by destroying the chance ones reaching the skin afterwards from the air or hands, etc. Moreover, if a physician's hands have been covered with a sulfonamide containing cream, micro-organisms which leave those hands may carry with them their own pharmacotherapeutic nemesis.

What I have said is perforce fragmentary, but I hope that it will serve to bring out three principal points.

First that the mechanisms through which antiseptics in the wider sense is accomplished on the skin are not usually through the intrinsic antiseptic properties of the agents applied but

rather by means of aiding, intensifying, or restoring the skin's natural protective devices.

Second, that all measures used in the antiseptics of normal skin must possess an absolute minimum of harmful effects upon the skin itself, otherwise the interference with powerful, natural protective forces will often vitiate any intrinsic antiseptic properties the measures may possess.

Third, that the recognition of the above facts inevitably leads to the conclusion that studies on skin antiseptics (including the evaluation of old remedies and the development of new ones) require a drastic reorientation. In order to gain valid information regarding desirable and undesirable effects of cutaneous antiseptic procedures, it is imperative to study by all possible techniques the effects accomplished and the changes brought about when the remedies are applied to the living human skin, rather than to study their effects on other organs, or in fluids or cultures or test tubes.

The therapeutic index of a cutaneous antiseptic measure cannot be established except on the skin itself, for both antiseptic activity and harmful effects often depend on mechanisms which are peculiar to the living skin *in situ* and on conditions which cannot be duplicated elsewhere.

Dr. MODELL. I find myself for the most part in agreement with Dr. Sulzberger. He has pointed out that chemical agents may act in many ways to rid the skin of bacteria, and that these may include materials which have little or no power to kill bacteria. Most people who do something on the skin to prevent infection have in mind that the substance they are using will kill bacteria. They place great faith in the value of this action. I have taken the position that such an action is of little value under the conditions of actual practice, and may be harmful. I think that this is substantially what Dr. Sulzberger has stated.

Dr. CATTELL. I hope we can discuss these problems further, but we have more ground to cover. Dr. Marshall, I wonder whether you would take up the use of local antiseptics in the urinary tract.

Dr. V. F. MARSHALL. Dr. Modell mentioned the urologic procedure of irrigating the bladder and questioned whether it kills germs in the bladder. Recently a heroic attempt was made to sterilize the bladder, primarily with the idea of killing a virus which might be the cause of papillomatosis. Fifty per cent phenol and glycerine were introduced in the bladder. Whether the patients so treated will get papillomas is very difficult to determine, because they have had so much trouble. However, the treatment did not sterilize the inside of the bladder. In fact, invariably these patients developed in-

fection as a result of the damage to the bladder wall.

It has been shown numbers of times that it is difficult to infect a normal bladder; that is, one which empties itself well. If you put virulent cultures into the bladders of dogs, only a small percentage develop cystitis, and those cases clear up rather quickly. But if you injure the bladder, by poking or scratching the surface, or radiating with x-ray or radium, the same cultures infect readily.

In irrigating the bladder we don't think we are sterilizing the surface of the bladder wall. We know we are not. Several beneficial things are accomplished, however. Primarily, it constitutes a mechanical cleansing of the bladder. Infected bladders usually have a great deal of mucoid matter, pus, etc., which is washed out. Stagnant urine is removed. Drainage is promoted, and any infection which drains well is more likely to be taken care of by the body forces. The other thing which has to be remembered is that a large number of our patients have residual bladder urine. Organisms apparently multiply rapidly and very well in the warm residual urine. We believe that, if you leave some mild antiseptic in the bladder, the residual urine will have bacteriostatic properties that it would not otherwise have. In short, we don't do bladder irrigation with the idea of sterilizing the bladder by the action of the irrigating agent.

In urologic surgery we sometimes use only soap and water for skin preparation. This is most frequently done in operations on the external genitalia. One reason is because in these areas blistering occurs easily after the stronger chemicals which we use on the skin elsewhere. I have no impression that in those instances there is any greater incidence of infection than in those patients prepared in the standard manner. We routinely use soap and water preparation for transurethral resections, frequently ligating the vasa at that time, and I don't recall here either that the incidence of infection is higher than in those done after alcohol and iodine preparation.

The other question is that of the sterilization of the urethra. It apparently cannot be done without damaging the urethra. There have been a number of attempts made to do this. You can reduce the bacterial population by irrigating, but you cannot get rid of the organisms completely or permanently. It is much like the skin.

DR. CATTELL: There is one more organ which we would like to have considered before we ask for general discussion. I wonder whether Dr. McLean would say something about the possibility of sterilization in the eye.

DR. McLEAN: There is not very much to be said which has not already been said. Dr.

Modell mentioned the outstanding exception, the accepted Credé method for preventing ophthalmia neonatorum, and there is no question about the way that it has reduced the incidence of ophthalmia neonatorum. Otherwise, with external ocular infection, particularly conjunctivitis, there seems to be little room for argument as to what is effective and what is not, and in the more serious cases of conjunctivitis there seems to be nothing chemical which can be introduced in the eye which is anywhere nearly as effective as repeated simple irrigations which remove the excess pus and debris which tend to collect in the eye and impede normal drainage. I must except, of course, as we did in the beginning, the sulfonamides and quite likely the mold extracts.

It is very true, though, that there is a long list of local antiseptics which may be dropped into the eye. I can't begin to remember them all. Under various trade names, they include many metallic salts, both inorganic and organic, particularly those of silver, mercury, copper, zinc, and some benzene ring preparations. By and large they are sufficiently diluted so they don't do very much harm, but I don't believe you can say much more for most of them. The irritant properties of many of them help to increase the flow of tears, and thus enhance cleansing.

There is one apparent exception in the case of angular conjunctivitis. This is caused by the Morax-Axenfeld bacillus, which secretes a proteolytic enzyme. The symptoms are promptly arrested by the use of a solution containing a zinc ion (usually the sulfate or the chloride). However, the action is not bactericidal, for the bacillus grows well in culture media containing zinc. The zinc ion has its symptomatic effect by inhibiting the enzymatic proteolysis.

So far as sterilization of the eye and the surrounding skin before operation is concerned, that is another problem. We use approximately the same technic as Dr. Child outlined for preparing the surrounding skin of the lids, face, and brow, and we use simple irrigation of the conjunctival sac in the hope that we will mechanically get rid of some of the organisms which may be there. We do use mild silver protein just before irrigation, not because we believe that silver protein in one form or another is going to sterilize anything but because it makes it easier both mechanically and visually to insure a thorough irrigation, which is made until the returns are clear, using the silver protein as an indicator.

I would like to ask Dr. Modell one question. If you were to undergo a major surgical procedure, how would you like your skin prepared and how would you like your surgeon to prepare his hands?

DR MODELL I would want the surgeon to take every precaution not to introduce more bacteria into my body than were already there. The instruments, the drapes, the dressings, and all the other paraphernalia should be made just as sterile as possible. I don't doubt that the washing of the surgeon's hands is desirable, simply on the basis that the gloves might tear. I certainly would want him to wear sterile gloves when he operates on me. I would demand a good cleansing of my skin with soap and water, which is, I think, about as good a preparation of the skin as can be obtained.

DR McLEAN Would you like to have his hands soaked in alcohol or any other solution either before or after washing?

DR MODELL I wouldn't care.

DR McLEAN Would you object to it?

DR MODELL No, I don't think it would make any difference as long as they were washed for ten minutes.

DR McLEAN Would you object to anything besides soap and water on your skin?

DR MODELL I don't think painting with a colored substance is at all harmful.

DR McLEAN How about the fatty solvents, benzene, ether, and what not?

DR MODELL I think they are unnecessary.

DR McLEAN I am trying to find out what you would want.

DR MODELL I would insist on a cleansing with soap and water. I don't think anything else accomplishes more.

DR CHILD Could I comment on one thing? Scrubbing the skin should be a gentle procedure, because anything which tends to cause a serious ooze defeats the purpose of cleansing. We saw that beautifully demonstrated in the laboratory not so long ago in experimental animals.

DR MODELL Dr Child, how do you prepare the field in the region of the rectum for, let us say, a hemorrhoidectomy? What skin sterilizing procedures do you use there?

DR CHILD I use nothing more than soap and water. Others apply various dyes to a vehicle which will not cause a chemical dermatitis. Soap and water, I think, is the most desirable preparation.

DR MODELL This would indicate that soap and water will serve satisfactorily in the preparation of a most highly contaminated operative field in a surface full of crypts and folds. It should, therefore, be adequate for the preparation of the abdomen.

DR SULZBERGER I think that this may be one of the rare occasions on which I can come to the aid of a surgeon. When one removes "soil" by scrubbing with soap and water it requires a certain amount of mechanical energy or friction.

The amount of friction necessary may perhaps be reduced by using a combination of grease solvents and soap and water washings. The dissolving of the grease and the softening of the film in which the bacteria and other elements of the soil are imbedded permits the easier emulsification and washing off by soap and water.

DR CATTELL Isn't soap more effective?

DR SULZBERGER I believe that either grease solvents or soap-and water washings soften and remove soil even when used alone, but that with their combination you may perhaps get a sort of synergistic effect, which requires a minimum of friction and skin damage while effecting a maximum degree of surface cleansing and removal of micro-organisms.

DR CATTELL Those are agents which are not desirable from the standpoint of the skin, such as benzene and alcohol.

DR SULZBERGER Of course organic solvents may often be harmful because they remove too much of the natural oils and skin greases. This holds true particularly on skins or in skin areas which have an inadequate grease producing capacity or when the solvents are used too long or at oft-repeated short intervals.

DR MAISEL I don't know why sulfonamides and penicillin were excluded from the discussion, for it seems to me that those are the agents to which most people are now attempting to orient themselves.

DR MODELL I believe the sulfonamides will stand by themselves and so will penicillin and other antibiotics. This discussion should serve to emphasize their importance by helping to eliminate a lot of chemicals now used. From the report of the pharmacist, Mr. Clark, we learn that last year we used for the hospital, not including the college, about 4,000 gallons of alcohol. Today alcohol is a critical material. Its usefulness in preparing the skin before hypodermic injection is dubious at best, and certainly useless when we consider that no one allows it to remain for more than one instant before the needle is plunged into the skin. Does anyone think we have a vital procedure here? Does it do anything more than make the needle-prick hurt more than it would without alcohol on it?

DR WHEELER I think anyone who cleans the skin with alcohol before injecting should not think he is sterilizing the skin but rather that it is just a convenient and good-smelling way of cleaning it. I would be willing to use anything else if it were equally convenient. Soap, I am sure, could be used with equal results.

DR MODELL I would like to point out that it is a fairly common procedure for the nurse to put an alcohol sponge on the sterilized needle while it waits for the doctor. Since bacteria

can be cultured from most of the 70-80 per cent alcohol used, this little bit of nursing technic reduces the sterility of the whole injection procedure.

DR. CATTELL: Except for the extra trouble, it appears that the results would be probably better from soap and water.

DR. WHEELER: I don't think they could be better, because the results from alcohol are perfect.

May I ask a question? Dr. Sulzberger, in a disease like impetigo, a bacterial infection of the skin, do you feel that the use of local applications is worthless?

DR. SULZBERGER: No, the use of local applications is surely valuable, but a good deal of what they do is mechanical. It has been demonstrated that the vigorous use of soap and water and petrolatum sometimes brings results just about as good and as prompt as white ammoniated mercury. Furthermore, white ammoniated mercury without measures which remove the crusts does little more than inhibit autoinoculations.

DR. GOLD: Do you think we could get general agreement on the need for at least one year's experience in New York Hospital with the use of soap and water for all kinds of skin preparations in all situations in which antiseptics have been used in the past for presentation at another conference next year?

DR. CATTELL: It would be fine if we could. Apparently surgical technics are already going along those lines.

## Summary

DR. MODELL: A therapeutic procedure practiced more widely than any other by both physicians and the laity is the application of a chemical for the purpose of destroying bacteria on the mucous membranes and the skin. The agents referred to as local antiseptics or disinfectants

are used in the form of swabs, instillations, irrigations, sprays, etc. The spot is dabbed with alcohol before every injection. The skin is painted with iodine and washed with alcohol, or treated by some other antiseptic, before surgical operations. The bladder is irrigated with an antiseptic wash. The conjunctiva is flushed with a solution containing an antiseptic. There are numerous other practices of a similar nature. The discussion omitted such special materials as the sulfonamides and penicillin and centered on the less specific antiseptics which are the ones most widely used. These are general protoplasmic poisons and they are presumed to be efficacious against all kinds of bacteria.

The value of local antiseptics is challenged. The discussion brought forth the fact that local antiseptics never sterilize skin or mucous membranes. In spite of their striking power in test-tube experiments, the conditions prevailing in infections of the skin and mucous membranes are such that the net result of their routine use is not beneficial to the patient, and frequently harmful. The exceptions are few. The practice of applying a solution locally for its germicidal action creates a sense of security against infection which appears to have no basis in fact. Thorough washing with soap and water wherever possible seems to do all that can be accomplished in the way of reducing the bacterial population of the skin. Irrigation with saline alone seems to be as effective as when chemical antiseptics are added to the wash. The firm entrenchment of local antiseptics in the minds of the physician and laity seems to depend chiefly on the test-tube result, theory, hope, and tradition.

How the antiseptics act, why their suggestive efficacy in the laboratory experiment fails to materialize in their use on human tissues, and how their use may promote rather than retard infection, were among the subjects developed in today's discussion.

---

## REGISTRY OF VETERINARY PATHOLOGY ESTABLISHED

Recently an arrangement was approved by the Surgeon General of the U.S. Army and the board of governors of the American Veterinary Medical Association for the establishment and maintenance at the Army Institute of Pathology, Army Medical Museum, Washington, D.C., of a Registry of Veterinary Pathology. This registry will become a unit of the American Registry of Pathology, an organization operating by the authority of the Surgeon General under the sponsorship of the National Research Council. Material submitted should be addressed to Director, Army Institute of Pathology, Army Medical Museum (attention Registry of

Veterinary Pathology), 7th and Independence Avenue S.W., Washington 25, D.C. The director will be glad to furnish further instructions to contributors for submission of material to the Registry of Veterinary Pathology. The members of the Special Committee on Registry of Veterinary Pathology are W. H. Feldman, Mayo Foundation, chairman; Capt. Charles L. Davis, V.C., Army Institute of Pathology; Harry W. Schoening, chief, Pathological Division, U.S. Bureau of Animal Industry, and, member ex officio, Lt. Col. Baldwin Lucké, M.C., deputy director, Army Institute of Pathology.—*J.A.M.A.*, Sept. 16, 1944

# Postgraduate Medical Education

*Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (428 Greenwood Place, Syracuse); George Bachr, M.D., and Charles D. Post, M.D.*

## Poliomyelitis

THE Suffolk County Medical Society will meet for postgraduate instruction on December 6 at 6:30 P.M. at Friede's Inn, Smithtown.

A lecture will be given by Dr. Philip M. Stimson, associate professor of clinical pediatrics at Cornell

University Medical College, who will speak on "Poliomyelitis."

This instruction is presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

## Rheumatic Fever

A TEACHING Day on rheumatic fever and rheumatic heart disease was held at the Syracuse University College of Medicine on November 30 under the auspices of the Cayuga, Cortland, Onondaga, and Oswego county medical societies, the Medical Society of the State of New York, the New York State Department of Health, and the Syracuse University College of Medicine.

The afternoon meeting, held in the auditorium at 2:00 P.M., was called to order by Dr. Herman G. Weiskotten, Dean, Syracuse University College of Medicine. The chairman of the meeting was Dr. J. G. Fred Hiss, professor of clinical medicine at the Syracuse University College of Medicine. The program consisted of four lectures: "Etiology, Epidemiology, and Diagnosis of Rheumatic Fever and Rheumatic Heart Disease," by Dr. T. Duckett Jones, associate professor of medicine, Harvard Medical School; "Treatment of Rheumatic Fever," by Dr. Albert D. Kaiser, associate professor of pediatrics, University of Rochester School of Medicine and Dentistry; "The Prevention of Recurrences in the Known Rheumatic Patient," by Dr. Homer F. Swift, Hospital of the Rockefeller Institute for Medical Research; and "The Need for a Public Health Program for the Care of the Rheumatic Child," by Dr. David D. Rutstein, Deputy Commissioner of Health, City of New York Department of Health.

Questions to be asked on the lectures were written

down and discussed at the panel meeting in the evening.

Several exhibits were shown at the Syracuse University College of Medicine. They included: "The Proposed Plan of Operation of the Syracuse District Cardiac Program," demonstration of a model, by Dr. J. G. Fred Hiss; Metropolitan Life Insurance Company, Dr. George M. Wheatley, assistant medical director; "Laboratory Diagnosis," by Dr. O. D. Chapman, professor of bacteriology and parasitology at the Syracuse University College of Medicine; "Case-Finding and Follow-Up Care (Physicians, Public Health Nurses, and Other Agencies)," by Dr. C. A. Sargent, District State Health Officer, and Franziska Glienke, R.N., District Supervising Nurse.

Dinner and the evening meeting were held at 7:00 P.M. in the University Club of Syracuse. Dr. Brewster C. Doust, professor of pediatrics at Syracuse University College of Medicine, was chairman of the meeting. The Syracuse District Cardiac Advisory Committee, which consists of Drs. O. D. Chapman, B. C. Doust, J. G. Fred Hiss, M. W. Kogan, O. W. H. Mitchell, G. C. Sincerbeaux, S. A. Ver Nooy, and H. G. Weiskotten, was introduced. The program consisted of a lecture, "The Proposed Plan of the Syracuse District Cardiac Program," by Dr. J. G. Fred Hiss, followed by a panel discussion with the following speakers: Drs. J. G. Fred Hiss, T. Duckett Jones, Albert D. Kaiser, H. M. Marvin, D. D. Rutstein, and Homer Swift.

## General Medicine

POSTGRADUATE instruction in general medicine was given before the Steuben County Medical Society on November 9 at 12:30 P.M. at the Wagner Hotel in Bath.

The lecture was "Treatment of Jaundice"; it was delivered by Dr. William F. Lipp, assistant in medicine at the University of Buffalo School of Medicine.

## Penicillin Therapy

INSTRUCTION in penicillin therapy was given to the Franklin County Medical Society on November 15 at 3:00 P.M. in the nurses' classroom, Alice Hyde Memorial Hospital, in Malone. Dr. Paul C. Clark, assistant professor of clinical medicine

at the Syracuse University College of Medicine, delivered a lecture entitled "Penicillin Therapy."

This instruction was presented as a cooperative endeavor between the Medical Society of the State of New York and the State Department of Health.

## CLINIC DIRECTORY

16,000 copies of the *Directory of Venereal Disease Clinics* (Supplement No. 4 to *Venereal Disease Information*, Revised 1944) have been distributed. Free copy supply is exhausted. Copies can be bought from Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C.,

at 15 cents per copy (special prices for large quantities).

Purchasers other than State Health Departments should obtain authorization forms from the U.S.P.H.S. before ordering this or other P.H.S. VD films.—VD War Letter, Aug. 30, 1944

## SHRINKAGE IN MINUTES

1:52 P. M. Inferior and middle turbinates are highly engorged and in contact with the septum. The airway is completely blocked.

2:01 P. M. Maximum shrinkage has been obtained 9 minutes after two inhalations from Benzedrine Inhaler. The airway is open.

## LASTING FOR HOURS

3:15 P. M. Airway is still open. Benzedrine Inhaler produces a shrinkage equal to, or greater than, that of ephedrine.

4:00 P. M. Two hours after treatment, shrinkage persists. Benzedrine Inhaler shrinkage lasts 17% longer than that of ephedrine.

## ***A better means of nasal medication***

In reporting their carefully controlled investigation of vasoconstrictive drugs, Butler and Ivy state that inhalers and sprays are preferable to nasal drops, and are—in most cases—"the better means of nasal medication."

Arch. Otolaryng., 39 109-123, 1944.

Each Benzedrine Inhaler is packed with racemic amphetamine, S.K.F., 200 mg.; oil of lavender, 60 mg.; and menthol 10 mg.

Smith, Kline & French Laboratories, Philadelphia, Pa.

## Physicians' Home Makes Annual Financial Report

THE Trustees and the Board of Directors of the Physicians' Home have submitted the following financial report:

1. The amount and location of real property owned by the Corporation is as follows:

A plot of land at 171 Joralemon St., Brooklyn, New York (assessed 1943-1944—\$20,000.00).

2. The amount of the personal property owned by the Corporation, its location, and the manner in which it is investigated are as follows:

(a) Cash in banks—September 30, 1944

<i>Unrestricted funds</i>	
The Chase National Bank—City of N.Y....	\$ 10,801.09
Stamford Savings Bank.....	972.69
Bank for Savings.....	1,048.76
	<u>\$ 12,822.54</u>

<i>Restricted Funds</i>	
Excelsior Savings Bank.....	\$ 7,731.69
Dry Dock Savings Bank.....	4,783.67
Stamford Savings Bank.....	2,045.04
	<u>\$ 14,560.40</u>
<b>TOTAL.....</b>	<u><b>\$ 27,382.94</b></u>

(b) Investments

	Issuer	Market Values
15 M	United States of America, 2 1/4% Treas. Notes due 4/31/54.....	\$ 16,200.00
2 M	United States of America, 2 1/4% Treas. notes due 9/15/72.....	2,020.00
25 M	United States of America, 2 1/4% Defense Savings Series G.....	25,000.00
7 M	City of New York, 3% Corp. Stock Water Supply '77.....	7,560.00
10 M	Baltimore & Ohio R.R. Co., 6% Refd. Bonds, Series C '95.....	6,400.00
5 M	N.Y.C. & H.R. R.R. Co. 1st Mort., 3 1/2% due '97.....	4,750.00
5 M	Penna. R.R. Co. Genl. Mort. C, 3 1/4% due '70.....	5,300.00
5 M	Atlantic Coast Line R.R. 1st Mort., 4% due '52.....	5,150.00
5 sh	Rochester Gas & Elec. Co. Pfd., 6% series D.....	540.00
4 sh	Calumet & Hecla Copper Comm.....	26.00
5 sh	Penna. R.R. Co. common stock.....	150.00
5 sh	Beacon Chocolate Co.....	.....
		<u>\$ 73,096.00</u>

(All said securities being held in a safe deposit box of the Corporation in the vaults of the Chase National Bank of the City of New York)

3. The amount and nature of the property acquired by the Corporation during the period beginning October 1, 1943, and ending September 30, 1944:

(a) Securities Purchased

U.S.A. Defense Savings Bonds Series G.....	\$ 11,000.00
15 M Railroad Bonds.....	14,450.10
	<u>\$ 25,450.10</u>

(b) Cash

Cash on hand October 1, 1943.....	\$ 3,425.37
Dues and contributions.....	37,539.89
Income from investments.....	2,199.48
	<u>\$ 43,164.74</u>
<b>TOTAL.....</b>	<u><b>\$ 68,614.84</b></u>

4. The amount applied, appropriated, or expended during such period, and the purposes, objects, or persons to or for which such applications, appropriations, or expenditures were made, as follows:

General expense, postage, appeals, etc.....	\$ 796.31
Maintenance of beneficiaries.....	5,919.25
Investments purchased.....	\$ 25,450.10
Loss on sale of investment.....	197.99
	<u>\$ 32,363.65</u>
Cash balance in general operating fund 9/30/44.....	\$ 10,801.09

B. WALLACE HAMILTON, M.D., Treasurer

## Medal Awarded Dr. Spencer for Cancer Service in 1944

ORGANIZATION of all cancer activities on a national scale was advocated on October 31 by Dr. R. R. Spencer, chief of the National Cancer Institute, Bethesda, Maryland, in a speech accepting the Clement Cleveland Award for outstanding

service during 1944 in the effort to control cancer by education.

The presentation of the award, a palladium medal named in honor of one of the founders of the

### HYDROCHLORIDE

Brand of MEPERIDINE HYDROCHLORIDE  
(Isonippecaine)

*Winthrop Chemical Company, Inc.*

Pharmaceuticals of merit for the physician • NEW YORK 13, N. Y. • WINDSOR, ONT.

[Continued from page 2618]

American Cancer Society, was made to Dr. Spencer by Dr. Frank E. Adair, the Society's president, at the eighteenth annual dinner of the New York City Cancer Committee at the Cosmopolitan Club, 122 West 66th Street. Dr. John C. A. Gerster, chairman of the committee, presided, pointing out that the dinner launched the annual booth campaign conducted in New York November 1-15, for the dual purpose of spreading public knowledge of cancer, through more than one hundred booths set up at strategic locations in the city, and collecting funds for the committee's \$100,000 annual budget. According to vital statistics nearly 40 people a day die from cancer in New York City alone, Dr. Gerster said.

For the purpose of national organization, Dr. Spencer suggested that "special cooperative committees" be selected from members of the various cancer research foundations, from the American Cancer Society, the American Association for Cancer Research, the National Cancer Foundation, and other institutions that are actively engaged in cancer control, prevention, or therapy.

"The National Cancer Institute desires to accept its share of this responsibility," Dr. Spencer said.

"Preventive medicine is rapidly becoming an ever-increasing factor in modern practice, and health education is the very soul of prevention. We see clearly that while research and the acquisition of new knowledge about cancer are essential, such knowledge must continually be shared. There is always a cultural lag between new knowledge and its application. The taxpayer has the right, not the privilege, to be kept informed.

"Under the provisions of the National Cancer Institute Act, the dissemination of 'information through the appropriate publications for the benefit of health agencies and organizations, physicians, and any other scientists and for the information of the general public' is a mandated responsibility of which we cannot divest ourselves. However, health education is only a part of our program. We are interested in promoting *all* phases of cancer control, prevention, and therapy—the education of the public, the education of physicians, which includes the setting up of full-time departments of oncology or cancer biology in medical schools, the establish-

ment of preventive clinics, the provision of adequate diagnostic service, the cooperation with states in developing cancer control divisions within the framework of state departments of health, and the continuation of organized research into the causes, the diagnosis, the prevention, and the treatment of cancer."

The citation from the award committee, of which Mrs. Robert G. Mead is chairman, accompanying the medal stated:

"The Committee has, by unanimous vote, elected you as the recipient of the medal for 1944, because of the outstanding services you have rendered to the movement for cancer control. By virtue of the very office that you hold as chief of the National Cancer Institute your influence is far-reaching, and your contribution during the past year in articles written for the layman has without doubt greatly aided in the educational work of cancer control, for which this award is given. Your most recent effort to aid the work of the newly formed organization, The National Foundation for the Care of Advanced Cancer Patients, all seem to make you worthy in some measure of our recognition."

The award was established in 1937. The first recipient was Henry Luce, editor of *Time*. Others who have been honored in past years include Mlle. Eve Curie, Dr. Elise S. L'Esperance, and Dr. Frederick L. Hoffman.

Dr. Spencer has been chief of the National Cancer Institute since 1943, having served as assistant chief since 1938. The Institute was founded by act of the Seventy-fifth Congress in 1937, when a sum of \$750,000 was appropriated from the public treasury for the erection of a building and an annual appropriation of \$700,000 was authorized. Dr. Spencer received the gold medal of the American Medical Association in 1930 for his discovery of a preventive vaccine against Rocky Mountain spotted fever.

In a statement read at the dinner, Dr. Thomas Parran, Surgeon General of the U.S. Public Health Service, declared:

"Tonight, in awarding D. Spencer the Clement Cleveland medal, you have honored a great scientist and a great teacher who has never lost sight of the fact that science is an abstraction until it becomes the servant of the people."

### New Army Statement on Requirement and Use of Physicians

THE requirements of the Surgeon General to maintain the established strength of Medical Corps officers on active duty will be met through the appointment of medical ASTP trainees and medical students holding inactive commissions in the Medical Administrative Corps and by calling to active duty Medical Corps officers who are on inactive status for further training as interns, junior residents, or senior residents at nonmilitary hospitals.

Accordingly, appointments in the Medical Corps, Army of the United States, will not be made direct from civil life except for assignment to active duty with the Veterans Administration.

All appointments resulting from applications

processed in accordance with this directive will be in the Medical Corps, AUS, for assignment to duty with the Veterans Administration only. Every effort must be made to persuade candidates whose applications are processed under these instructions to accept this appointment.

Recalcitrant physicians, including interns and residents, will not be reported to Selective Service.

Qualified candidates who of their own volition may apply for commission in the Medical Corps and who cannot be processed under these instructions will be advised that a great need exists within the Navy and Public Health Service and will be urged to contact the appropriate offices for information regarding these services.

### Navy, U.S.P.H.S., and Veterans' Administration Still Need Physicians

PAUL V. McNUTT, chairman of the War Manpower Commission, announces that he has been informed by the War Department that recruitment of civilian physicians for the Army has been dis-

continued. At the same time he announces that recruitment for the Navy must continue, since it has urgent need for approximately 3,000 additional

*with Confidence*

Through all the years, the name Koromex has always stood for dependability. Koromex Jelly today has attained its highest spermicidal effectiveness. Koromex Cream (also known as H-R Emulsion Cream) is equally effective, and is offered as an aesthetic alternative to meet the physiological variants. Prescribe Koromex with confidence. Write for literature.

HOLLAND-RANTOS COMPANY, INC. • New York, Chicago, Los Angeles

[Continued from page 2620]

medical officers. The U.S. Public Health Service and the Veterans Administration are also continuing to recruit physicians, Mr. McNutt said.

Vice Admiral Ross T. McIntire, chief of the Bureau of Medicine and Surgery, U.S. Navy, informed Mr. McNutt that personnel expansion and intensification of operations in the Pacific have precipitated a grave shortage of medical officers.

"With less than 13,000 medical officers on active duty in the Navy, the procurement of at least 3,000 more as soon as possible is imperative," said Admiral McIntire. "Even this figure will not meet actual needs but would ease the emergency that now exists; physicians and surgeons whose availability has been or may hereafter be certified by the Procurement and Assignment Service, WMC, should lose no time in obtaining particulars for commissions in the Navy Medical Corps by communicating with their nearest office of Naval Officer Procurement."

Mr. McNutt said he had been informed that the Army will fill its future requirements for military physicians from sources now available to the Army and thereafter will not require certification of availability of additional physicians from the Procurement and Assignment Service of the War Manpower Commission. There are now about 47,500 physicians on duty as medical corps officers of the Army. This probably includes those serving with the Veterans Administration and other governmental agencies to which the Army Medical Corps assigns its medical corps officers.

Mr. McNutt said that there are at present roughly 60,000 physicians in the armed forces and the Veterans Administration. The total number of physicians in the armed forces represents approximately 40 per cent of the active medical profession of the United States.

In addition to the 3,000 medical officers needed at present by the Navy, the Public Health Service has

need for approximately 300 for the U.S. Coast Guard and other agencies.

In informing Mr. McNutt of the termination of the Army recruiting of physicians except for the occasional specialist, Maj. Gen. Norman T. Kirk, Surgeon General of the Army, said, "The large number of physicians now in the Army volunteered for commissions without regard for their personal interests. The U.S. Army Medical Department is appreciative of the fine service they have given. Their removal from their usual practice also represents a sacrifice on the part of all civilians, who have had to get along with less medical care than they obtained in peacetime."

The Veterans Administration has, and will continue throughout the duration of the war emergency to have, assigned to it medical officers in the Army and the U.S. Naval Reserve to care for the needs of the casualties in its charge, the War Manpower Commission said. Doctors whose applications are at present in process for appointment in the Army Medical Corps will be considered for appointment and assignment to duty with the Veterans Administration, the War Manpower Commission statement added.

Mr. McNutt said that the War Manpower Commission joins with the directing board of its Procurement and Assignment Service and the War Department and the Office of the Surgeon General in expressing appreciation of the sacrifice involved in cooperation that was necessary on the part of physicians and the public before the Army reached its present level of medical personnel.

Mr. McNutt also expressed the hope that additional civilian physicians will respond to the Navy's appeal for more doctors to apply for commissions. The needs of the U.S. Public Health Service and the Veterans Administration, he said, although much smaller than those of the Navy, are nevertheless important.—*J.A.M.A.*, Nov. 4, 1944

## Parran Appoints Head of Mental Hygiene Division

DR. THOMAS PARRAN, Surgeon General of the Public Health Service, Federal Security Agency, today announced the appointment of Dr. Robert H. Felix as medical director in charge of the Mental Hygiene Division in the Bureau of Medical Services, Public Health Service. Dr. Felix relieves Dr. Lawrence Kolb, who retired October 31.

Dr. Felix, who took charge of the Mental Hygiene Division on November 1, said that his first effort would be the development of a well-balanced program for the advancement of mental health in the United States.

"Such a program," he explained, "will require the coordinated effort of all organizations—both public and private—having an interest in the prevention and control of mental disease. Present needs for improvement in the control of mental disease include expansion of research and a nationwide extension of psychiatric services to apply the findings of research to the psychic problems of the people.

"More research in mental and nervous diseases is needed, both because of the magnitude of the problem in civilian and military groups, and because of the uncoordinated nature of existing knowledge on the causes, extent, treatment, and control of these most prevalent of disabling illnesses. A coordinated and expanded program would seek further knowledge on the fundamental causes of

mental disease; methods of early diagnosis; evaluation of existing technics in psychotherapy; and experimentation in new technics. Research also should throw further light on psychosomatic relationships in health and sickness.

"Application of existing knowledge and skills should be widely extended through an expansion of psychiatric services in State mental institutions and in other State and community organizations, whether public or private. The present supply of psychiatric personnel is too small to permit the provision of consultant services in all parts of the country. A first objective, therefore, is to stimulate more training of psychiatrists, psychiatric social workers, clinical psychologists, and psychiatric nurses and attendants. Training should be undertaken at the undergraduate level among professional students in order that coming generations of physicians, social workers, and nurses will have a general understanding of mental disease, psychosomatic relationships, and psychotherapy. Postgraduate training should be expanded for those who wish to make psychiatry and its related specialties their career."

Dr. Felix was born in Downs, Kansas, May 29, 1904. He received his degree in medicine at the University of Colorado in 1930, and interned at the Colorado General Hospital at Denver.

He was granted a two-year fellowship by the

Commonwealth Fund and took this postgraduate training at the Colorado Psychiatric Hospital under Dr. Franklin R. Ebaugh.

Dr. Felix was commissioned in the regular corps of the Public Health Service in August, 1933, and was assigned to the Medical Center of the Bureau of Federal Prisons at Springfield, Missouri. The assignment was in line with the responsibility of the service for the provision of medical and psychiatric services in Federal penal and correctional institutions.

When he was transferred to the Public Health Service Hospital at Lexington, Kentucky in 1936, Dr. Felix was clinical director at Springfield. During his stay at Lexington he served as clinical director and later as executive officer of this institution for the medical and psychiatric rehabilita-

tion of narcotic drug addicts. In September, 1941, the service sent him to the Johns Hopkins University School of Public Health for one year of postgraduate work in public health administration, with emphasis on psychiatry. He received a master's degree at Johns Hopkins in June, 1942.

With the advent of war, Dr. Felix was sent in 1942 to the U.S. Coast Guard Academy at New London, Connecticut, where he developed and operated a mental hygiene service for Coast Guard cadets and applied psychologic and psychiatric tests in the selection of officer material.

Dr. Felix is a fellow of the American Medical Association, the American College of Physicians, the American Psychiatric Association; a member of the Association of Military Surgeons, and the Southern Psychiatric Association; and a past president of the Kentucky Psychiatric Association.

### American Physicians Art Association Announces Prize Contest

FOR the best art works by physicians memorializing the medical profession's "Courage and Devotion Beyond the Call of Duty" (in war and in peace), \$34,000 in War Bonds will be given as prizes.

This prize contest is open to any physician mem-

ber of the American Physicians Art Association, including medical officers in the armed forces of the United States and Canada.

Full information is available on request to the sponsor, Mead Johnson & Co., Evansville, Indiana, U.S.A.

### American College of Surgeons Expands Graduate Training Program

IN EXPANDING its program of graduate training in surgery to assure adequate opportunities for advanced training in surgery, particularly for recent medical graduates when they return from service with the armed forces, the American College of Surgeons has enlarged its headquarters staff in Chicago and announces the following new appointments effective immediately:

Maj. Gen. Charles R. Reynolds (MC, Retired), former Surgeon General of the U.S. Army, has been appointed Consultant in Graduate Training in Surgery. General Reynolds was in the Army from 1900 to 1939; served in the Philippine Insurrection; was Chief Surgeon of the Second Army, A.E.F., in the first World War; was Commandant of the Army Field Service Medical School, Carlisle, Pennsylvania, from 1923 to 1931; and was Surgeon General of the Army from 1935 to 1939. He has been Director of the tuberculosis control program of the Pennsylvania State Health Department for the past four years.

Dr. George H. Miller, formerly Dean of the Faculty of Medicine and Chairman and Professor of the Department, American University of Beirut, Lebanon, Syria, has been appointed Director of Educational Activities. Dr. Miller served in the U.S. Army Medical Corps, A.E.F., in 1918 and 1919; was associate professor of pharmacology and later associate professor of medicine of the State University of Iowa College of Medicine between 1922 and 1932; and was with the American University of Beirut from 1932 to 1944.

The Department of Graduate Training in Surgery is under the general direction of Dr. Malcolm T. MacEachern, chairman of the Administrative Board, working with that Board, and responsible to the Committee on Graduate Training in Surgery, of which Dr. Dallas B. Phemister, of Chicago, is chairman, and to the Board of Regents. In addition to General Reynolds and Dr. Miller, the staff of the department consists of Dr. Paul S. Ferguson, Director of Surveys, and three assistants who conduct the surveys, and the field representatives conducting the regular hospital standardization surveys under the direction of Dr. E. W. Williamson, Assistant Director of the College, who assist as required in the graduate training program. The latter is a development of the basic work of the College in stimulating the improvement of hospital service. Surveys of hospitals for graduate training in surgery have been conducted since 1937 by the College.

When the war ends in Europe, in order to satisfy the demands of men whose training in surgery was interrupted by war service, together with those of current medical graduates, sufficient opportunities should be ready to offer approved training to men who wish to become surgeons, Dr. MacEachern declares, adding that a competent surgeon, according to present-day ideas, requires a preparation of three or more years of systematic, supervised graduate training in general surgery or a surgical specialty, following a general internship and graduation from an acceptable medical school.

### American Urological Association Offers Award

THE American Urological Association is offering an annual award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deems none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to

urologists who have been in such specific practice for not more than five years. All interested should write the Secretary for full particulars.

The selected essay (or essays) will appear on the program of the forthcoming June meeting of the American Urological Association.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before March 15, 1945.

[Continued on page 2626]

# *Unimpeded Response*

## BECAUSE OF

# DEPENDABLE SAFETY

New hope for the sufferers from acne, psoriasis, and keratosis follicularis is substantiated by an extensive and rapidly growing bibliography which describes the beneficial results obtained with massive dosage of vitamins A and D.\*

Because of the systemic nature of these resistant skin affections, the indicated massive dosage of vitamins A and D must be administered uninterruptedly for relatively long periods, in order to obtain maximal response. This continuous, intensive treatment is possible only when a non-toxic form of medication is chosen for administration.

**APOLARTHON**, the only high potency preparation of vitamins A and D derived entirely from natural sources, has proved to be a dependably safe, and effective method of treating such skin diseases as acne, psoriasis and keratosis follicularis.

*\*Complete bibliography on request*

Each capsule of Apolarthron contains 25,000 U.S.P. units of natural vitamin D and 30,000 U.S.P. units of natural vitamin A. Available on prescription through all pharmacies in packages of 60 capsules.

**J. B. ROERIG & COMPANY**  
536 Lake Shore Drive • Chicago 11, Illinois

## Transcriptions for Health Broadcasts

THE Bureau of Health Education of the American Medical Association offers a new service to county and state medical societies having difficulties in keeping up radio broadcasting to the public because of shortage of personnel. Scripts to be read by local doctors or used as a basis for new or rewritten material prepared locally have been available for many years and may still be had. In order, however, to meet the local personnel shortages, the Bureau has now prepared several series of electrically transcribed radio broadcasts available to state and county medical societies and auxiliaries or to local groups approved by the state or county medical societies.

These broadcasts may be used with a minimum of time-consuming local preparation and participation.

At the present time, four series are available for broadcasting to the public and one series for use in connection with health teaching in elementary schools. The blue circular that accompanies this Bulletin lists the series of broadcasts available and indicates the method of procuring them, namely, by borrowing complete sets from the Bureau of Health Education without expense to the local society except the nominal cost of shipping the records back when they have been used.

The distinction between the two types of transcriptions offered should be noted. The series in-

tended for broadcasting direct to the public are available on loan. One series entitled "Health Heroes" for use in schools is offered for sale only because it is necessary for a school to own these records in order to make the best use of them. The price is \$25 per set of 12 programs on six two-sided 16-inch records. In order to use them in schools, one of two arrangements must be made: (1) the school must have a central record-playing instrument with loudspeakers in classrooms or a portable record player; or (2) arrangements must be made with the local radio station to play these records at a convenient time, and radio receiving sets must be supplied to the classrooms. These teaching helps will fit in the curriculum. The scripts furnished enable the teacher to become familiar with the program in advance and thus make the best possible use of it in her teaching. Orders for these records should be accompanied by a remittance or official purchase order from the local board of education. Local medical societies or auxiliaries might wish to purchase sets of these records for presentation to the schools as an act of cooperation and evidence of good will.

These electrically transcribed recordings must be used on broadcasting-type turntables or record players revolving at 33 revolutions per minute; they cannot be played on home-type phonographs which revolve at 78 revolutions per minute.

## Pennsylvania Public Relations Council Publishes First Annual Report

THE Council on Medical Service and Public Relations of the Medical Society of the State of Pennsylvania has published its first annual report, for the year 1943-1944.

Among the subjects reported on are the work of the Medical Service Association of Pennsylvania and the Emergency Maternity and Infant Care Program.

## County News

### Albany County

Miss Marion Sheehan, director of the State Division of Public Health Nursing, has been named secretary of the New York State Temporary Commission on Medical Care.\*

### Bronx County

The regular monthly meeting of the county society was held at Burnside Manor on November 15 at 8:30 p.m.

Two papers on the role of penicillin were presented. Dr. Max Weiss spoke on its use in medical conditions, and Dr. Edward R. Cuncliffe's phase of the subject was the use of the drug in surgical conditions. Dr. Emil Koffler discussed Dr. Weiss' paper and Dr. Thomas M. Brennan discussed the paper by Dr. Cuncliffe. A general discussion followed.

All members of the county society have been asked to fill in a questionnaire on health insurance. The statistics gathered from the answers will be used as criteria on medical insurance problems.

The Bronx Gynecological and Obstetrical Society held a meeting on October 27. Dr. Abraham B. Tamis gave a case report on "Persistent Brow Presentation," which was followed by one entitled

"Persistent Mentoposterior Position—Pomeroy Maneuver," by Dr. Jacob Clahr. Dr. A. Charles Posner and Dr. Irving J. Kushner presented a paper, "Craniotomy—A Review of the Cases at the Bronx Hospital." Discussion was by Dr. Meyer Rosensohn.

Dr. David I. Bassett gave a case report on "Optic Neuritis and Sinusitis" at the November 28 meeting of the Bronx Otolaryngological Society. Dr. William Silverstein discussed the report.

### Broome County

The regular monthly meeting of the county society was held November 14 in the auditorium of the Binghamton City Hospital at 8:30 p.m. The scientific program consisted of a lecture entitled "Clinical Evaluation of Thiouracil in the Treatment of Hyperthyroidism," by Dr. Maurice J. Whitelaw.

### Dutchess County

A regular meeting of the county society was held in the pavilion of the Hudson River State Hospital, Poughkeepsie, November 8 at 8:00 p.m. The scientific session featured an address on "Traumatic Surgery" by Dr. John J. Moorhead, professor of surgery, Post-Graduate Medical School, and Chief of Surgery, Post-Graduate Hospital, New York City.

### THE CIVILIAN DOCTOR'S RESPONSIBILITY

The physicians of the United States have an enviable record in the war. Those in the armed forces both by their quality and by their numbers have cooperated in the finest program of medical care ever developed for any army or navy. More than 55,000 physicians left their civilian positions, and those who remained at home took over most of the medical care that had been previously given by those entering the service. Theirs too has been a tremendous, physician is caring for thousands of people gone from each portion of the young men and women. Those who remained those who were not physically qualified and therefore required more attention per capita than the group cared for by physicians prior to the war.

This load has resulted in an increase in morbidity and mortality in the medical profession. While some advantages, particularly increased income, accrued to these physicians, they have shortened their lives and impaired their health in meeting this extra task.

At present only a sufficient number of physicians remain in civil life to meet the needs of the civilian population, provided they are properly distributed.

In an attempt to aid such proper distribution, the Procurement and Assignment Service of the War Manpower Commission limited recruiting in certain states and facilitated over three thousand three hundred relocations. However, perhaps as a result of what seems to be the impending end of conflict, a tendency has developed on the part of some physicians to move into other areas of practice or to enter postgraduate or other special training rather than to remain in their present essential job of meeting the needs of the community that depends on them for medical care.

The medical profession itself requested that a federal agency be set up by which the members could voluntarily supply the armed forces with necessary medical care and as a part of that federal program to continue minimal adequate care for the civilian population. The number of physicians considered essential in the second and third years of the war was set for its attainment. Each physician who is in an essential position should remain in that capacity until present shortages of physicians can be relieved. The excellent record of the medical profession both in peace and in war should not be marred by any sudden exodus at this time to meet the call of greener interesting fields or more lucrative pastures.—*Editorial, J.A.M.S., Aug. 19, 1944*

## IN WHOOPING COUGH ELIXIR BROMAURATE

IS A UNIQUE REMEDY  
OF UNIQUE MERIT

Cuts short the period of the illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

GOLD PHARMACAL Co., New York

[Continued from page 2626]

### Greater New York

The Greater New York Dental Meeting will hold its twentieth annual session December 4-8 at the Hotel Pennsylvania in New York City.

### Jefferson County

The annual meeting of the county society was held on November 9 at the Black River Valley Club. Dinner, at 6:30 P.M., was followed by a scientific program—"Glaucoma," by Dr. Walter Atkinson.

At the meeting the following officers were elected for 1945:

Dr. Harlow G. Farmer, Watertown, president; Dr. Sumner E. Douglas, of Adams, vice-president; Dr. Lawrence E. Henderson, of Watertown, treasurer; Dr. Charles A. Prudhon, of Watertown, secretary; and censors, Drs. Leon L. Sampson, of Alexandria Bay, Sutherland E. Simpson, of Watertown, Earl E. Babcock, of Adams Center, Frederick R. Calkins, of Watertown, and Harold L. Cokey, of Alexandria Bay. The committee chairmen will be reported later.

### Nassau County

A campaign of education on cancer to reach every man, woman, and child in Nassau County will be undertaken during the coming year by the Nassau County Cancer Committee, it was revealed at the first fall meeting of the educational advisory committee of that organization. A mail campaign to raise \$25,000 in funds for the purpose began on November 1.

The Rev. Joseph A. Smith, of West Hempstead, chairman of the advisory committee and a director of the parent committee, presided over the meeting, which was attended by twenty-three representatives of county-wide organizations.

A cancer study outline, prepared by Nassau County educators and physicians, now in use in the Nassau schools, has been taken over by the American Cancer Society for nation-wide distribution.\*

### New York County

Dr. A. J. Ginsberg, a member of the county society, was the first practicing physician to receive the Army-Navy E award, according to announcement made in New York. At a ceremony at the St. Moritz Hotel October 25, the presentation was made for the Army by Col. Edgar W. Garbisch, Corps of Engineers, District Engineer, New York district, and for the Navy by Lt. Comdr. John D. Cassidy, USNR, Third Naval district. Dr. Ginsberg received the award for himself and the Q.O.S. Corporation, of which he is both president and active member. The corporation has, since before Pearl Harbor, been making binocular stereoscopes for all branches of the service to use in reconnaissance. The excellence of the binocular stereoscopes has caused them to be used on all battlefronts in detecting enemy camouflage, in making maps, etc. Dr. Ginsberg, who four years ago had a large short-wave therapy exhibit at the Academy of Medicine, maintains an active practice in addition to his corporation activities.

Sister Elizabeth Kenny, Australian nurse-discoverer of the Kenny treatment for poliomyelitis, arrived in New York City October 24 as the guest of one of the city's newspapers and on the invitation of the Division of Communicable Diseases of the

New York State Health Department. She brought with her a film to be shown to medical men here depicting case histories of infantile paralysis patients treated by the Kenny method. The film, which it took four years to make, was shown to organized groups of medical men of the city.

The Clinical Society of the New York Diabetes Association has been organized with the following officers: Drs. John J. Weber, Brooklyn, chairman; Louis Bauman, New York, first vice-chairman; Edmund L. Shlevin, Brooklyn, second vice-chairman, and Harry G. Jacobi, New York, secretary-treasurer. The society is functioning under the auspices of the parent organization and is somewhat of an outgrowth of the clinics committee, which has now been dissolved. The society will consist of fellows, associate fellows, and members. A carefully selected founding group of specialists in diabetes will constitute the nucleus of the fellowship; this group will formulate standards for subsequent admission to fellowship and associate fellowship and will be the sole body which votes in future fellows. The board of directors of the New York Diabetes Association wishes to establish a representative founding group from among the specialists in the five boroughs and has appointed a nominating committee to examine credentials and to make recommendations. The new society will take over the establishing of standards for diabetes clinics in New York City and the vicinity. It will aim to bring about general adoption of these standards and for this purpose will recommend to the parent organization certification of individual hospital clinics adequately meeting its prescribed standards, as well as withdrawal of certification on delinquency. It will initiate, conduct, and publish statistical surveys on the basis of data derived from certified clinics. It will promote constructive relationships between physicians who are specialists in diabetes and representative physicians of allied medical specialties, such as ophthalmologists and surgeons, who will selectively be admitted to the fellowship. It will have contact with related technical groups such as dietitians, laboratory technicians, nurses and social workers through the "member" category. It will by close mutual association promote scientific understanding and conquest of problems in the management of diabetes, especially as these are encountered in clinical practice. The inaugural meeting was held at the University Club, October 26.

Details of a \$9,000,000 medical and research project jointly sponsored by the City of New York and Columbia Presbyterian Medical Center, which would include elaborate facilities for dealing with baffling tropical-disease problems arising from the global war, were disclosed yesterday by city authorities and officials of Columbia University.

Of the threefold project, involving proposed addition of three separate new building units to Medical Center, the two which have not been heretofore revealed in detail are a tropical-disease hospital and laboratories and a public health institute for teaching and research.

The third unit is the Nightingale Hospital, a cancer clinic, which was in the early stages of construction at Fort Washington Avenue and 163rd Street when the war intervened.

The consolidated program is designed to provide a center for research and teaching in fields where

present facilities are greatly inadequate. Its benefits will be offered to the entire nation, if not the world. Actual construction of the physical plant is partly contingent upon anticipated Federal funds which would come from postwar public works appropriations.

Dean Willard C. Rappleye, of the Columbia University School of Medicine, said it would be "one of the greatest centers of its kind in the world."\*

The November 3 issue of *Better Times*, official publication of the Welfare Council of New York City, is given over to a review of progress in public health work in New York City since the turn of the century, and to a preview of the major health problems yet to be met. It is dedicated to Bailey B. Burritt, known as the "father of the family health movement in New York City," who has retired as chairman of the executive council of the Community Service Society after thirty-one years of service.

Dr. Joseph Jordan Eller addressed the Waterbury, Connecticut, Medical Society at the Waterbury Club on Thursday, November 9, at 8:30 p.m. His subject was "Tumors of the Skin" (benign and malignant). The address was illustrated with lantern slides.

Capt. Ralph Schwartz, (MC), AUS, has been awarded the Silver Star for gallantry in action in Normandy, France, on July 29, 1944.

Comprehensive postwar plans for the development of a great medical-dental center in the Bellevue area by the New York University College of Medicine in cooperation with the City of New York and Bellevue Hospital were announced on October 26 at a dinner in the Hotel Roosevelt by Dr. Harry Woodburn Chase, chancellor of the university.

The dinner was in honor of Dr. Samuel A. Brown and Dr. George B. Wallace, senior faculty members of the N.Y.U. School of Medicine, each of whom was celebrating his seventieth birthday. Edward M. Bernecker, Commissioner of Hospitals; Bernard M. Baruch; and Dr. Donal Sheehan, acting dean of the N.Y.U. College of Medicine, addressed the audience of faculty members and alumni. Dr. Hervey C. Williamson, president of the college Alumni Association, presided.

The long-range plan as visualized by Dr. Chase would comprise three units:

1. A university hospital and diagnostic clinic which would offer all methods of modern diagnosis, together with inpatient facilities, to families of the middle-low income group, and placing the emphasis upon the maintenance of health and upon preventive medicine. It would be a center of co-ordination for all available medical services, including those of physicians; nurses, and social service workers.

2. An institute of medical sciences where the clinical departments of medicine can offer opportunities to younger men for study and research in specially important fields.

3. A medical library, hall of residence, and a large auditorium for postgraduate teaching to seat 500, "a place where the traditions of medicine can flourish and to which, after graduation, physicians can turn with pride for continued inspiration."\*

## Onondaga County

The November meeting of the county society and the Syracuse Academy of Medicine was held on November 14 at the University Club in Syracuse. Dr. Herbert H. Bauckus, of Buffalo, President of the Medical Society of the State of New York, spoke on "Medical Care Insurance—How to Make It Practical." The scientific address was presented by Dr. Paul C. Clark, of Syracuse. "The Treatment of Thyroid Disease with Thiouracil" was his subject.

At the October meeting Dr. Merrill C. Sosman, roentgenologist of Peter Bent Brigham Hospital of Boston, was the guest speaker. The title of his address was "Sarcoidosis, Erythema Nodosum, and Diseases Which Simulate Them."

## Putnam County

The county society has elected the following officers for 1944-1945: president, Dr. George H. Steacy, of Lake Mahopac; vice-president, Dr. Frank C. Genovese, of Patterson; secretary-treasurer, Dr. Garrett W. Vink, of Carmel.

## Queens County

Twenty-five years of combating tuberculosis in Queens was marked on November 20, at the annual meeting of the Queensboro Tuberculosis and Health Association, held at the Forest Hills Inn at 7:00 p.m.

Dr. James R. Reuling, president, gave a talk entitled "In Twenty-five Years," and Will Ross, president-elect of the National Tuberculosis Association, described "The Book with Too Many Pages." Percy H. Whiting, of the Dale Carnegie Institute, was toastmaster.

## Richmond County

How the United Medical Service plan for paying medical fees is a better solution to the present problems of society than the socialized medicine advocated by some organizations and individuals was described by Dr. Frederick Elliott at a meeting of the county society in the Richmond Health Center, St. George, on October 11.

Dr. D. V. Catalano, president, conducted the meeting.\*

## Schenectady County

The regular monthly meeting of the county society was held at the Ellis Hospital Library on November 7 at 8:30 p.m. The speaker was Dr. William Harvey Perkins, Dean of Jefferson Medical College, Philadelphia; his subject was "Host Types in Tuberculosis."

## Warren County

Dr. Morris Maslon, director of the Thomas H. Foulds Memorial Laboratory in Glens Falls Hospital, spoke on "Blood Plasma and Transfusion" at the institute for the public health nurses of Warren, Washington, and Saratoga counties on Friday morning, October 20.

During the afternoon session, Dr. R. F. Korn, New York State Department of Health, Division of Communicable Diseases, spoke on "Tropical Diseases." It was pointed out that New York State has no reason to fear an outbreak of any of the less common diseases with the return of servicemen. The transmission of diseases by mosquito, flies, lice, and rat fleas was emphasized, along with the newer findings for the elimination of this source of trans-

mission, plus the sanitary precautions being taken in the United States.

The newer developments in the field of communicable disease with the possibility of shortening the isolation period for patients with scarlet fever were considered.

School nurses from the three counties were present at the meeting as well as some of the Glens Falls Hospital nursing staff.\*

#### Westchester County

The one hundred forty-seventh annual meeting of the Medical Society of the County of Westchester was held at the New York Hospital, Westchester Division, White Plains, November 21 at 8:30 P.M.

The general topic of the meeting was: "The Future of Medicine in the United States." There was a panel presentation and discussion of this subject with Dr. Edward R. Cuniffe and Dr. Louis H. Bauer as the guest speakers and Drs. Adie, Archibald, Parsons, and Todd as discussants.

The outgoing and incoming presidents of the society delivered their retiring and inaugural addresses at this meeting.

The Westchester Cancer Committee is conducting its sixteenth annual appeal for funds to carry on its program of cancer control. This year the Committee is continuing its program of cancer education for the layman, and the further development of programs in cancer research already in progress under the direction of its Research Council and its Research Fellow, Dr. George Y. McClure.

Physicians are not asked to contribute to the work of the Committee or to canvass contributions from their patients, but if they have an opportunity to advise any of their patients or friends who happen to be in a position to contribute to this cause, it is hoped they will not fail to say a good word for the program. The names of the physician members, however, do not appear on the appeal sent to residents throughout the county.

The Westchester Cancer Committee is composed entirely of physicians except for the treasurer and legal counsel, who are a banker and a lawyer.

A round-table discussion of poliomyelitis was held at a special scientific meeting of the county society to be at New York Hospital, Westchester Division, on October 24.

Dr. Win H. Watters, orthopaedic surgeon at Grasslands Hospital and consulting orthopaedic surgeon at United Hospital, Port Chester, led the discussion, in which two guests, Dr. Nicholas S. Ransohoff, associate orthopaedic surgeon of the

Hospital for Joint Diseases, and Dr. Samuel Frant, epidemiologist and director of the Bureau of Preventable Disease of the New York City Health Department, participated.

Dr. Margaret Bashford, resident pediatrician at Grasslands Hospital, discussed the infantile paralysis epidemic in Westchester this year. Dr. F. Duncan Barnes, director of pediatrics at Grasslands and New Rochelle hospitals, discussed the diagnosis and early treatment of this disease. Dr. Donald R. Reed, attending pediatrician at Tarrytown, Dobbs Ferry, and Grasslands Hospitals, described unusual observations concerning incubation and contagion. Dr. William G. Grillo, anesthesiologist at Grasslands, told of new developments in meeting acute respiratory emergencies.\*

How the home and community can help the 500,000 victims of epilepsy in the United States adjust to their surroundings and lead normal, average lives, was described on October 23 by staff members of the Baird Foundation Clinic of Beth David Hospital, New York City, speaking at the Lincoln Park Jewish Center in Yonkers, through the courtesy of the Association for the Control of Epilepsy.

Joseph F. Stein, president of the center, is a director of the Baird Foundation and of the Association for the Control of Epilepsy.

Participants emphasized that the problem of epilepsy will be magnified in postwar years because of the frequency of seizures brought on by military head injuries.

Dr. Jerry C. Price, medical director of the clinic, and a staff member of the Neurological Institute, College of Physicians and Surgeons of Columbia University, told of strides made in development of medication in the last decade.

Harry Sand, administrator of the clinic and instructor of psychology at New York University, discussed the work of the clinic and the psychological aspects of treating and adjusting the epileptic patient to master his abilities. He pointed out that epilepsy has nearly the same incidence of occurrence as diabetes and active tuberculosis.

Dr. Kate Levine, psychologist at the clinic, formerly of Rockland State Hospital, described how the individual's behavior, emotional, and personality problems can be detected through tests and how these problems can be corrected.

The head of play therapy at the clinic, Miss Louise Wiener, cited specific cases in which the epileptic child had been helped to express himself and gain confidence.

Miss Lois Tompkins, social worker in charge of rehabilitation, described her contacts with families of epileptics. Also present were Miss Rosalind Finklestein, chief statistician of the clinic, and Mrs. Henry H. Benning, president of the Association for the Control of Epilepsy.\*

# Woman's Auxiliary

## To the Medical Society of the State of New York

### County News

**Broome County.** The Woman's Auxiliary of the Broome County Medical Society held its opening luncheon on October 7, in the Iron Fence tea-room.

Mrs. Manuel M. Monserrate, president, presided at the business session, at which plans for the year's activities were discussed and reports of the various committees were presented.

Mrs. Mark Williams, chairman of the committee on arrangements, was assisted by Mrs. C. R. Seymour, Mrs. Ronald L. Hamilton, Mrs. D. O. Chamberlain, Mrs. John Kane, Mrs. M. J. Whitelaw, Mrs.

William Ackroyd, Mrs. Carl Benson, and Mrs. Harold McNitt.

**Nassau County.** The regular meeting of the auxiliary was held in the Nassau Hospital Auditorium on Tuesday evening, October 31, at 8:15 p.m. The nurse recruitment program was the theme of the evening. The meeting was addressed by Mrs. Inez Johnson, Director of Nurse Recruitment for the Nassau County Chapter of the American Red Cross, who brought with her a nurse who has seen active service in one of the theaters of war. She told the auxiliary of some of her experiences.

### PAPER HOLIDAYS

"Paper holidays" are being declared in cities and towns throughout the country in an effort to stretch limited supplies of paper, the War Production Board announced on September 16. During the "paper holidays," retail merchants will use no bags or wrapping paper, except for articles that require wrapping for sanitary and protective purposes.

The W.P.B. Conservation and Salvage Divisions, in cooperation with the Periodical Publishers National Committee, will sponsor the "paper holidays."

The first "paper holiday" was held in Peoria, Illinois, early in July. Not only were large quantities of wrapping and packing materials saved during the holiday, but also paper salvage in Peoria increased 600 per cent as the public expanded its paper-consciousness. So successful was the Peoria drive that from a short-term holiday it was extended as a continuing program, officials said.

"Paper holidays" in other cities, based on the Peoria plan, may be declared for one week, one month, or for the duration. Even one day's curtailment in the use of paper will help, W.P.B. officials said. Howard Coonley, Director of the W.P.B. Conservation Division, stressed the need for stringent economies to conserve the nation's waning paper stockpiles. He said:

"Unlike many other wartime shortages, the paper problem shows no evidence of immediate solution even when the war in Europe ends. Enormous quantities of food, equipment, and medical supplies will still be needed overseas for our servicemen and for relief to distressed nations. All of these shipments require paper or paperboard for packaging."

Because some dealers still have stocks of packaging materials on hand, the public has not yet felt the pinch of shortages, officials said. With the ever-increasing paper needs for the armed services and essential home products, still further cuts must be anticipated in the near future, they added.

Harold Boeschstein, acting director of the W.P.B. Forest Products Bureau, commented:

"Military requirements of woodpulp for production of such products as explosives and high tenacity rayon for ties, as well as for overseas packaging and other uses, have reached the highest point of the war and are expected to step up in war theaters throughout the world.

"Substantial improvements in pulpwood production and waste paper collections during the first half of 1944 were not sufficient to balance the demands, despite further W.P.B. curtailments in supplies of paper for civilian uses."

Three groups of retailers—food, drug, and variety stores—throughout the nation have already signed a W.P.B. pledge to conserve bags and wrapping paper.

Now paper holidays provide a unique method of bringing all retailers in every community into the conservation campaign.

"If the 'paper holiday' has not come to your town, local merchants who are anxious to cooperate may secure a paper holiday kit containing detailed instructions and suggestions for organizing the campaign, from the Executive Secretary of their State Salvage Committee," the W.P.B. Conservation Division said.—*Release from the Office of War Information, September 16, 1944*

### ERADICATION OF TUBERCULOSIS

Our principal task now is to extend tuberculosis control activities so as to reach the greatest number of workers and their families in the shortest possible time, making full use of all private and public resources. With energetic use and concerted action, the final eradication of tuberculosis from the United States is well within our grasp.—*H. E. Hilleboe, M.D., and D. M. Gould, M.D., U.S.P.H.S., J.A.M.A., May 27, 1944*

### THE VICE OF THE VIRTUOUS

The peculiarity of ill-temper is that it is the vice of the virtuous. It is often the one blot on an otherwise noble character. You know men who are all but perfect, and women who would be entirely perfect, but for an easily ruffled, quick-tempered, or "touchy" disposition. This compatibility of ill-temper with high moral character is one of the strangest and saddest problems of ethics.—*Henry Drummond.—Reprinted from Illinois M. J.*

## BRAZILIAN SURGEON DOUBLES AS HEAD OF FINGERPRINTING BUREAU

Combining the talents of surgeon and police officer is a routine matter for Dr. Hubert Wallau, of Brazil, now in the United States to study traumatic surgery under the auspices of the Institute of Inter-American Affairs, an agency of the Office of Inter-American Affairs. Dr. Wallau is head of the Identification Division of his home state of Rio Grande do Sul, and in recent years has supervised the fingerprinting of more than 200,000 adults in the city of Porto Alegre alone.

According to Dr. Wallau, all adults in Brazil, whether citizens or foreigners, are required to carry identity cards issued by local or state police departments.

As a result, he has been called upon to direct the supervision of almost every adult in Rio Grande do Sul.

The identification system, he went on to say, has proved invaluable in his state in curbing crime and fighting espionage—Release from the Office of the Coordinator of Inter-American Affairs

## UNDETECTED PULMONARY TUBERCULOSIS

Pulmonary tuberculosis is present in a significant proportion of adult patients admitted to general hospitals and remains undetected during the hospital stay unless all patients receive routinely a chest x-ray examination. Such unrecognized tuberculosis is a hazard not only to the patients themselves but also to the hospital employees who may be exposed to it. One of the measures essential to the solution of this problem is routine chest x-ray examination of employees.

Although the discovery of tuberculosis among

importance. It is hoped, therefore, that hospitals, physicians, and others will give more recognition to the existence of this problem and to the need of a complete plan of action, including routine chest x-ray of all adult admissions as well as periodic examination of medical students, nurses and all other employees—N.Y. State Dept. of Health, Health News, May 8, 1944

## *Rich in the Essentials* **MOST FREQUENTLY DEFICIENT**

Studies of malnourished patients usually reveal that the faulty diets chosen by these persons are usually lacking in foods which are rich in vitamins, minerals, and proteins. Such diets are generally high in carbohydrate content, and contain foods low in the essential nutrients.

The balanced composition of Ovaltine is ideally suited to the correction of malnutritional states due to faulty dietaries. Its abundant content of minerals, complete

proteins, and vitamins supply those nutrients most frequently lacking. Appetite is usually no problem when Ovaltine is prescribed. The delicious taste of this food drink delights the palates of children and adults, and adequate quantities are consumed daily without coaxing or persuasion. Three glassfuls of Ovaltine per day correct the nutritional deficiencies of virtually any dietary, bringing the intake of essential nutrients to at least adequate levels.

THE WANDER COMPANY, 360 N. MICHIGAN AVENUE, CHICAGO 1, ILLINOIS

# SULFADIAZINE

## Lederle

The pneumococcus is one of man's most resourceful enemies. It digests proteins, rebuilding the fragments into a new protein common to all types of pneumococci. It synthesizes a great variety of complex polysaccharides, thus forming a powerful protective armor against the body defenses. It lurks normally on the mucous membranes of the nose and throat, ready to attack instantly if resistance is lowered, or if virulence becomes increased.

Sulfadiazine is now universally used for the treatment of pneumococcal pneumonia, as well as for streptococcal and staphylococcal pneumonias. The record of sulfadiazine in the medical literature is unsurpassed by that of any other sulfonamide. It has been universally acclaimed for its broad therapeutic range, exceptional effectiveness and low clinical toxicity, in hundreds of publications and in thousands of case-reports. Millions of recoveries from serious infections attest its efficacy.

Reap  
the Ill  
Wind

"It's an ill wind that blows no good," the old proverb declares. And the genius of medical men is giving new meaning to these old words.

For in the ill wind, the shattering, terrible wind of war, they are finding new facts . . . developing new skills . . . improvising new techniques . . . reaping new knowledge that will play a vast, important part in the building of that "better world to come."

COSTLIER  
TOBACCOS

Camel

(This salute is published by the makers of Camel, the cigarette that is proud to be a favorite with men who wear the caduceus, as well as men in all the other services — according to actual sales records.)

## DIURBITAL

**VASODILATOR • DIURETIC  
SEDATIVE • CARDIOTONIC**

**SOARING BLOOD PRESSURE** usually declines gradually, steadily, persistently with Diurbital\*.

**CARDIAC RELIEF ENSUES** through removal of oppressive fluids and improved myocardial nutrition.

**SYMPTOMATIC RELIEF**, control of dizziness, headache, nervousness, etc., is usually promptly achieved.

Each enteric coated **DIURBITAL** Tablet provides: Theobromine Sodium Salicylate 3 grs., Phenobarbital  $\frac{1}{4}$  gr., Calcium Lactate  $1\frac{1}{2}$  grs. Bottles of 25 and 100 tablets.

**In HYPERTENSION**  
the HEART also takes a beating

**SAMPLES AND  
LITERATURE  
PROMPTLY SENT  
ON REQUEST.**

# COLD FACTS

*concerning coughs due to colds*

**CETRO-CIROSE\*** provides palatable, effective relief for coughs due to colds.

**CETRO-CIROSE** has an unusually palatable cherry flavor, which makes it a particularly acceptable remedy for children and all taste-conscious patients.

**CETRO-CIROSE** is an effective vehicle for administering additional medication in your favorite prescription.

## Each Fluidounce Contains:

Codene Phosphate	½ grain
Chloroform	2 minims
Alcohol	1½ per cent
Fluid Extract of Ipecac	1 minim
Glycerin	240 minims
Potassium guaiacolsulfonate	8 grains
Sodium Citrate	18 grains
Citric Acid	6 grains

Flavored with Wild Cherry and Menthol

Cetro-Cirose is available in 1 pint and 1 gallon bottles. A pharmaceutical of Wyeth Incorporated, Philadelphia 3, Pa.

\*REG. U. S. PAT. OFF.

*Thou better name than all the family of fame.*

**F**ORTUNATELY, today, medical provision of "tranquility" for climacteric cases is more practicable than ever—with Hexital... a preparation assuring more complete control of psycho-physical disturbances through ample hormonal compensation and safe sedation. ¶ Hexestrol (significantly less toxic than stilbesterol) is the estrogenic factor in Hexital—

3 mg. in each tablet; phenobarbital, the sedative component—20 mg. to the tablet. As combined in Hexital, unpleasant side-effects of synthetic estrin medication are reduced to a minimum. ¶ Average daily dose (preferably upon retiring) is one tablet. Supplied 100 and 1000 to the bottle, in scored tablets—inexpensively priced. ORTHO PRODUCTS, INC., LINDEN, N. J.

DONNA

LEAVES

ALKALOIDS - APPROX 1/4 GR BELLADONNA

IN G.I. DISORDERS OF SPASTIC ORIGIN

Both neurogenic and myogenic tonus of the entire gastro intestinal tract have been found to respond to the spasmolytic effect of DONNATAL'S ingredients

Atropine, by interrupting myo-vagal connections, will relieve spasticity of the upper portion of the alimentary canal, thereby relaxing pylorospasm and tending to re-establish the normal type of gastric secretion. Scopolamine is noted for its sedation of the intestinal structures, and its consequent value in spastic constipation and irritated colon. A relaxing influence similar to that of atropine (though more marked) is exerted by hyoscyamine—upon smooth muscle of the G.I. tract, gallbladder and ureter, providing relief in gastric and hepato biliary colic, and in sphincter spasm.

Phenobarbital helps control the psychogenetic factor—so important in spastic pathologies—by sedation of the central nervous system, supported in certain cases by the central action of scopolamine.

Donnatal is available in bottles of 100 tablets, each tablet containing the formula illustrated above.

## Fast, Sustained, Unified Dual-Action

Neo-Synephrine Sulfathiazolate, a chemical union which provides powerful vasoconstriction and ample bacteriostasis—a most effective combination when dual action is indicated.

In uniting Neo-Synephrine with the minimum amount of sulfathiazole, all the outstanding properties of these two familiar therapeutic agents have been fully retained. The solution is equally effective on repeated administration—is of low toxicity and produces no appreciable side effects.

# Neo-Synephrine Sulfathiazolate

*Available as a 0.6% solution in a buffered approximately isotonic vehicle in 1 oz. bottles with dropper for prescriptions, and in 16 oz. bottles for office and hospital use.*

*Trade Mark Neo-Synephrine Reg. U. S. Pat. Office*

# ANATOMICAL SUPPORTS for PENDULOUS ABDOMEN

*Patient of stocky type of build before and after application of a Camp Support*

MANY obese patients delay seeking a physician's advice until the overburdened joints show arthritic changes or severe dyspnea or anginal pain develops.

Gastro-enterologists and other clinicians report that anatomical supports are efficient aids in the treatment of these patients. Fitted in a reclining position, Camp Supports, by reason of the fact that they support the pelvic girdle, hold the forward load up and back, giving relief to the lumbar spine. They reduce the drag of the viscera upon the diaphragm, helping to improve its action in respiration and circulation. Camp Supports are comfortable and economically priced.

Offices in CHICAGO • NEW YORK • WINDSOR, ONTARIO • LONDON, ENGLAND

## NIGHT TREATMENT SIMPLIFIED

By eliminating the need for hot water bottles, electric pads, hot towels, in the treatment of local inflammations, Numotizine not only simplifies the nursing procedure but permits the patient to relax and sleep without interruption.

By stimulating phagocytosis, increasing the local circulation and encouraging removal of the products of inflammation, Numotizine affords relief in such local inflammatory conditions as:

Boils • Painful throat conditions  
Bronchitis • Arthritic Pain

### NUMOTIZINE THE PRESCRIPTION CATAPLASM NUMOTIZINE

A single application of Numotizine will last for the duration of the night—providing effective decongestion and analgesia for eight hours or more.

# THE *Anatomy* OF A KEMP'S SUN-RAYED TOMATO

● Except for skin, seeds and core,\* all regions of this tomato are important to you in tomato juice. That's why we use the whole tomato, minus skin, seeds and core, for Kemp's Sun-Rayed brand Tomato Juice. Note proportion of three primary regions pictured above, left. Just right for finest flavor, high nutrition, rich red color and proper consistency. No ordinary field tomatoes these, but a special strain developed through 23 generations of tomato culture. We convert these tomatoes into Kemp's Sun-Rayed by our patented process which insures high retention of vitamins A, B<sub>1</sub> and C.

# RELIEF OF PAIN in Dysmenorrhoea

At every menstrual period some women suffer and they seek your advice for relief. Often even after exhaustive investigation, no organic basis can be found for this dysmenorrhoea, yet month after month it recurs. For such menstrual distress, 'Tabloid' 'Empirin' Compound provides dependable, safe relief.

The synergistic action of the acetylsalicylic acid and the acetophenetidin also eases the headache which often accompanies menstruation, while the caffeine combats depression.

Acetophenetidin . . . gr.  $2\frac{1}{2}$  (0.162 gm.)

Caffeine . . . gr.  $\frac{1}{2}$  (0.032 gm.)

Acetylsalicylic Acid . . gr.  $3\frac{1}{2}$  (0.227 gm.)

# WHEN THE *Restorative* POWERS OF TISSUE MUST BE AUGMENTED

In the management of burns and non-infected or infected indolent wounds, Morruguent Ointment has proved of highly beneficial influence on healing. Based on the unsaponifiable active principles present, Morruguent is 25% stronger than cod-liver oil, U.S.P. This greater content of the vitamin-bearing fraction, to which the stimulant influence on wound healing is attributed, accounts for the greater therapeutic value for which Morruguent has been acclaimed by so many physicians.

## MORRUGUENT

Wound odor disappears, necrotic material is liquefied, granulation tissue fills the wound, epithelization begins early, scarring is minimized. Morruguent Ointment is applied directly onto the wound, gauze covered, and the area lightly bandaged. Supplied in 2-oz. collapsible tubes, and in 1-lb. and 5-lb. jars.

# Written with Confidence!

The physician who prescribes Mandelamine in the treatment of urinary infections may rest assured that it will promote prompt and effective relief without danger of toxicity and irritation which are common occurrences when certain other urinary antiseptics are employed.

This freedom from by-effects makes Mandelamine of eminent value in the treatment of obstinate cases in which the medication must be continued for long periods of time. For the same reason, Mandelamine therapy is indicated when dealing with urinary infections in children, and during pregnancy.

Of definite advantage to the busy physician is the convenience of administration which Mandelamine offers through elimination of the need for routine urinary pH control, accessory acidification, adjustment of fluid intake, and dietary regulation.

## MANDELAMINE

Reg. U. S. Pat. Off. (Methenamine Mandelate)

Supplied in enteric coated tablets of 0.25 Gm. each, sealed, in packages of 120, 500 and 1000.

# Reasonable TREATMENT OF HYPERTENSION

Successful management of high blood pressure calls for a regimen which is adjusted to individual requirements. Physical activity is generally curtailed and overwork is avoided. In certain circumstances special diets are prescribed and the use of stimulants is restricted.

These measures are often supplemented with the administration of Theominal. This combined vasodilator and sedative aids in reducing blood pressure to a more normal level. As a consequence hypertensive symptoms are relieved and the risk of complications is reduced.

**DOSAGE:** The customary dose of Theominal is 1 tablet two or three times daily; when improvement sets in the dose may be reduced. Each tablet contains theobromine 5 grains and Luminal\* ½ grain.

\*Luminal (trademark), Winthrop Chemical Company, Inc., brand of phenobarbital.

## Theominal

Reg. U. S. Pat. Off. & Canada

# Announcing **Desenex**

## A *Specific* for the Superficial Fungous Infection **ATHLETE'S FOOT**

Desenex, a new development of the widespread war research, represents the successful therapeutic application of fatty acids for the treatment of this prevalent and stubborn condition.

The active ingredient of Desenex is undecylenic acid. This unsaturated fatty acid is as harmless to the skin as stearic acid, which is widely used in cosmetics. Surprisingly, however, this generally inert substance is as specific and potent in its action on fungi as some widely used chemotherapeutic agents are on other organisms.

Desenex may be used with confidence. Clinical cure of the troublesome fungous infection—athlete's foot—is generally achieved within a relatively short time by daily application of Desenex.

# The Good Companion

**T**RADITIONALLY, bread goes well with practically any food. So it is natural for bread to bolster up the wartime diet, which may be shy of important foods from time to time.

Nutritionally, bread is a food for energy, protein and protective factors. The first two characteristics have long been recognized. And now specifications, agreed to by the Baking Industry and government nutrition authorities, call for enrichment of all white bread with vitamin and mineral factors—thiamine, riboflavin, niacin and iron in significant amounts.

diets that approach prescribed vitamin and mineral requirements.

That is why present popularity of sandwiches and extra slices of bread with otherwise skimpy wartime meals need not dismay the physician. Bread has kept pace with recent discoveries in biochemistry and nutrition.

## Bread is basic

{ This is one of a series of messages run in the interests of the Bakers of America, by the makers of Fleischmann's Yeast. }

In fact, with the better protective bread of today, it is easier and more natural than ever before to eat normal

# Therapy in Nutritive Failure

IN MANY, if not most disease states, the therapy of nutritive failure is important in hastening convalescence and restoring the patient to a state of health.

*The four essentials for therapy in nutritive failure include . . .*

1. **DIET:** 4,000 calories, 150 gram protein, rich in vitamins and minerals.
2. **BASIC THERAPY:** Thiamine, riboflavin, niacinamide, ascorbic acid, orally.
3. **ADDITIONAL MEDICATION:** Synthetic vitamins as indicated orally or parenterally.
4. **NATURAL B COMPLEX:** Brewers' Yeast or extract, or rice bran extract, and/or liver extract orally or parenterally.

They provide **BASIC FORMULA VITAMIN TABLETS** for intensive **BASIC THERAPY**—note their content:

10 mg. Thiamine Hydrochloride  
50 mg. Niacinamide  
5 mg. Riboflavin  
75 mg. Ascorbic Acid

This is the basic formula used by Drs. N. Jolliffe and T. D. Spies and described by the latter in his paper on Nutritional Rehabilitation of 100 American workers for Industry.

Squibb also provides the synthetic vitamins indicated for additional medication as well as the *natural B Complex* factors—the fourth essential therapy of nutritive failure.

*Sold to druggists in bulk. . . . Prescribe as few or as many tablets as may be needed. . . . The cost per tablet is surprisingly low. . . . Write for literature.*

## Squibb Basic Formula Vitamin Tablets

# Announcing

## INCREASED POTENCY

..For greater therapeutic effect

Now you can abundantly provide all the factors of the B Vitamin for severe "B" depletion—with Vitamin "B" Soluble (Walker). The potencies of Thiamin, Riboflavin and Niacin have been doubled and the fortifying Vitamin C has been trebled.

Vitamin "B" Soluble (Walker) is derived from brewers yeast. It therefore contains various known and unknown factors that are only found in the natural source.

The added Vitamin C gives marked biologic assistance to Vitamin B—a fact which has been clinically manifested in improved pathology of the upper respiratory mucosa.

### A Presidential Message

*To the Members of the Medical Society of the State of New York:*

Based on the experience of the Western New York Medical Plan, whose progress I have watched since its inception, I have reached certain conclusions about what features a medical prepayment insurance plan should have.

I believe that the best plan consists of surgical and obstetrical coverage with a "rider" providing for medical care for those who want it and are willing to pay the added cost. All of this should be on the indemnity principle.

It has not been found practical to have a clause calling for co-insurance or deductible qualifications. The Western New York Plan found that requiring a patient to pay for the first call did not reduce unnecessary calls after the first few calls. Furthermore, such stipulations are a hindrance to good medicine and to preventive care.

There should be no wage ceiling for those wishing to subscribe to a plan. Medical insurance should be regarded as by no means

complete protection but as a contribution to the cost. If it covers most of the cost, it has made an important contribution. Without a ceiling, there is no class discrimination and all get the same service. This is the policy in the sale of voluntary hospital insurance plans.

It is impossible to enforce the requirement of a wage ceiling. In practice no real investigation is made, and if an investigation is made the patient will resent what he considers an intrusion into his private affairs. Often, too, the physician feels that the patient is earning above the ceiling and that he ought to pay more. The result is that any ceiling breeds distrust on the part of both the doctor and the patient.

When there is no wage ceiling requirement, the insurance element changes the physician-patient relationship very little. Since the plan is understood to be merely a contribution to indemnify the patient, there is less objection than is the case when the physician informs him that owing to his being above a certain income status, the charge will be the regular fee instead of the lower

rate set up for those in the lower income brackets.

It is generally conceded that the fee schedule for the low-income group should be that of the Workmen's Compensation Schedule. Few doctors would think of charging more than the rates on this schedule to a person earning \$2,000. The physician is in the best possible position to know what the patient is really able to pay. It is best neither to take from him his right to fix the fee nor his obligation to make it reasonable. When he is visited by a person well able to pay his full fee, he should let him know before the services are rendered that the insurance coverage will not compensate him in full. Complete service plans mean eventually that the physician will receive substandard pay and in the end substandard service will result.

The indemnity contract has written in it the schedule of fees to be paid the doctor by the insurance plan. The bill for the entire service is sent by the physician to the offices of the indemnity plan and the part of the fee which has been stipulated is paid to the physician. If there is a charge additional to this, the executives of the plan notify the patient of this fact. This operates as a check.

Limitations, such as for pre-existing diseases, must, of course, be made in the contracts. One form of good contract gives unlimited surgical and medical care *in the hospital*, within range of the Workmen's Compensation Schedule, with an allowance of \$50 for obstetrics, the balance to be paid by the subscribers. (This does not provide

for specialists' services.) Most plans make the greatest use of the general practitioner with greater limitation on specialists' services calling for higher fees.

It is possible to offer such coverage, including 30 house or office calls per year for the subscriber and 15 for each dependent to the family, for \$36 a year. The same coverage can be provided for a single individual for \$15 a year.

In addition to the coverage specified above, this contract does make certain specific allowances for specialists' services. For instance, for any one disability a maximum benefit of \$5.00 is allowed for consultation with a specialist an equal sum for a special examination. Also, during one year each subscriber and his dependents are allowed a sum of \$10 for each of a number of special medical services, such as diagnostic x-ray service and physiotherapy. Such a limitation of specialist service was found necessary when, for example, under the Western New York Plan's old contract, it was found that everybody with throat trouble wanted a specialist and every woman wished her children to go to a pediatrician. This entailed considerable increase in cost and could not be afforded at the premium rate offered.

One word of caution is necessary. It is natural that from year to year certain modifications of the contract have to be made. This can be done only if every contract expires at the end of a year and is renewed at that time.

HERBERT H. BAUCKUS, *President*

## Recent Events

In view of the emphasis upon the insurance approach to the problem of the cost of illness, the experience of Rhode Island with its "Cash Sickness Fund" will be of interest. Says the *Rhode Island Medical Journal*<sup>1</sup> editorially:

"With more than a year's experience the State Cash Sickness Fund is now in a position to be more clearly evaluated as a factor in the social security program for the people of Rhode Island.

"Recently the Unemployment Compensation Board administering the sickness fund reported that for a period of five months—April through

August—the fund had paid out about \$100,000 more a month in benefits than it had taken in through payroll deductions in the same period. . . ."

The public press of the state, when this fact was announced, called for an investigation raising the question whether there might be connivance between unscrupulous workers and doctors of easy conscience to account for the cost. The *Rhode Island Journal* feels that in the lay mind doctors are thought of as physicians and must be willing to accept the onus of criticism when the matter of certification for illness is in

question For it is by such certification that benefits from the State Sickness Fund are gained by insured persons This procedure is common to all insurance plans and is an additional reason why such plans need the active cooperation of medical men having the highest degree of personal probity, the first reason being professional competence based on good medical education and thorough training In this instance, however,

"It should be carefully noted that the broadness of the definition in the Fund Act of sickness, and the too liberal attitude of the General Assembly through the years in allowing the title of 'Doctor' to be used without any explanatory degree, permit anyone short of a doctor of philosophy to attest certification for workers' benefits

"Our leading newspaper calls editorially for an investigation, presumably only of the recent increase in expenditures for benefits We call for a review of the entire program, possibly by such a group as the State Advisory Council on Health appointed by the Governor earlier this year to " clarify the extent to which the people wish to compensate themselves for loss of employment due to sickness by a better interpretation of the definition of illness in this particular act Such a review might establish a means by which the entire program may be more clearly interpreted to the people in terms of social protection Such a review might better advise the General Assembly in its decision on amendments proposed by the administering board or other reputable authorities

"Basically the sickness-act program is one of social relief and not of insurance for too many incalculable variables constantly enter into the problem to make sickness determinable in advance It is upon the law of probability of regular recurrence of events when great numbers of those events

contrary, the dominant motive in the establishment of every system of health or sickness insurance is the relief of poverty, not the preservation of the public health "

This observation is particularly apt at this time It is to be anticipated that further efforts will be made by the Administration to push its compulsory "health" insurance legislation, in spite of the fact that voluntary prepayment plans are everywhere getting under way in a real attempt to underwrite sickness As to sickness compensation the *Rhode Island Journal* comments further

"The medical profession of this State, however, has committed itself to the support of cash sickness

compensation to offset the loss of income of the wage earner due to his illness

"But the sickness compensation program belongs to the people, not to the State, nor the medical profession, nor any other group licensed to practice the healing art And to the people must be presented the complete problem

"There has been too little clear thinking on the distinction between the financial, economic, administrative, and health phases of the act As we have stated, the Fund is not aimed at the preservation of health Yet it involves all those who profess to the healing art by reason of the certification of the sickness of the claimant Thus the onus is placed upon the doctor, who must not only fulfill his primary professional responsibility for adequate diagnosis and treatment of his patient but who must also serve the State as a guardian of the financial status of the group

"The insured individual naturally wishes a generous benefit in his particular case Because sickness is not clearly definable by law, and as it is defined by insurance laws it is not identical with sickness as regulated by medical science, the doctor will naturally have a tendency to certify an applicant for cash benefits that may not be permitted under tightly construed legal qualifications

"Therefore, in not submerging his natural relationship to the patient so as to administer stringently the economic phases of the law the doctor by no means indicates opposition to the program, nor a lack of cooperation He merely acts in time-honored manner, and as the people—his patients—require He knows that any tendency to accede to the patient's demand for certification in excess of that which sound insurance law and a reasonable premium permit, involves the necessity from the administrator's viewpoint of controls to protect the fund He knows, too, that the problem of medical certification is inherent and must be dealt with so as to minimize difficulties

"Simons and Sinai point out in *The Way of Health Insurance* that 'the most startling fact about the vital statistics of insurance countries is the steady and fairly rapid increase in the number of days the average person is sick annually and the continuously increasing duration of such sickness Various studies in the United States seem to show that the average recorded sickness per individual is from seven to nine days per year It is nearly twice that amount among the insured population of Great Britain and Germany, and has practically doubled in both countries since the installation of insurance '"

We feel that comment of this kind cannot be too frequently brought to the attention of our membership The problem of medical certification is indeed the *sine qua non* of all insurance and must be faced realistically whether we contemplate government "health" insurance or any other plan As more insurance of this kind is written the problem will become more widespread

and the medical profession as a matter of course must be prepared to face charges of collusion and other fraudulent practices as an inevitable sequel.

The participation in the plans of as many

reputable physicians as possible, is the best security for the insured as well as the best answer to possible charges of abuse of insurance funds.

### Acute Osteomyelitis—Closed Treatment

In bygone years acute osteomyelitis was treated surgically as soon as the diagnosis was made, and the infected area was widely explored. In contradistinction to this older viewpoint, which still exists in many quarters,<sup>1,2</sup> a new school has risen which has adopted dilatory tactics.<sup>2</sup> In their hands a trial period of five to ten days is made, during which it is hoped the bone infection may localize, and then can be drained with greater ease and safety and better conservation of the bone. The advent of remarkable therapeutic agents, such as penicillin and the sulfa drugs, has led to further modification of the treatment of acute osteomyelitis so that its threat as a surgical emergency is waning.

The modern objective in overcoming infection is the destruction of the causative agent. The secondary injury caused by the invading organism can then be best repaired. Acute osteomyelitis is a disease which readily lends itself to these principles, for it is a general infection with localization in bone, caused most commonly by the staphylococcus aureus, or other cocci which are amenable to specific therapy. A group of surgeons<sup>3</sup> has subjected a series of patients with acute osteomyelitis to this medical point of view with unorthodox results. Supportive measures such as transfusion, infusions, serum, and vitamin and dietotherapy were also liberally used. Fifty-six patients were treated under this regime, with surgical intervention as a major

variation. Thirty underwent incision and drainage operations in the customary fashion, and 26 were treated without drainage but had aspiration, largely for diagnostic purposes. Twenty-one of 30 patients treated by drainage had lingering, draining sinuses, while but 9 had healed completely. Of the 26 cases treated medically 21 healed without sinus formation. There was only one death in the entire group. It is clear that the morbidity can be reduced if surgical drainage is not universally employed in the treatment of acute osteomyelitis.

Acute osteomyelitis is undergoing constant therapeutic revision, as are all diseases whose causative agent is susceptible to the action of penicillin and sulfa drugs. It may well be that the early institution of such therapy by eradicating the general septic features of such diseases will permit the local manifestation to heal spontaneously or with a modicum of surgery. Like empyema, acute osteomyelitis promises, at least in many cases, to fall in the category of combined operations—by internist and surgeons—the methods of one or the other or both successfully prevailing.

### Changes in Registration of Physicians in New York State

Many members of the Society have been confused by receiving bills for registration from the Division of Professional Education in Albany for four dollars instead of two dollars. This change is due to the fact that registration is now for two years instead of one year.

The change was approved by our Council on February 10, 1943, as an amendment to the Medical Practice Act which was subsequently passed by the Legislature.

Registration cards with checks should be in the office of the Division of Professional Education by January 1, 1945. Under the law the fine for delay of payment is one dollar for each thirty days or part thereof.

This ruling does not apply to physicians already in the service or those who will be in service before January 1, 1945.

It is recommended, however, that all physicians who are entering the service inform the Division of Professional Education of their removal from practice so that their records will be clear when they return.

COUNCIL COMMITTEE ON PUBLIC RELATIONS AND ECONOMICS

# *Symposium: Etiology, Diagnosis, Treatment, and Prognosis of Essential Hypertension*

## **MEDICAL TREATMENT OF UNCOMPLICATED HYPERTENSIVE VASCULAR DISEASE**

DANA W. ATCHLEY, M.D., New York City

IT IS difficult to restrain one's temptation to introduce this discussion of the treatment of essential hypertension with a series of don'ts. Certainly a most significant part of our progress in the past twenty-five years is the discovery that much of our interference with these patients has been unnecessary and even, at times, harmful. However, I shall postpone these comments, and attempt a somewhat more logical approach.

The natural first step of such an approach should be the enumeration of methods for removing the basic cause of the disease, or at least some suggestions that would result in slowing its progress. Unfortunately, we know nothing of practical significance about the organic causes of hypertensive vascular disease in man, in spite of the brilliant series of experiments on other animals that was initiated by Goldblatt. The incidence of hypertension due to unilateral renal disease has disappointingly turned out to be too small for serious consideration. Many clinicians hold the firm opinion that the advance of this disease can be inhibited by reducing the level of arterial tension, but there has been little evidence of a clear correlation between prolonged elevation of blood pressure and the incidence of serious complications and I am, therefore, not entirely convinced that this assumption is correct. Nevertheless, it is not unreasonable to recommend to the hypertensive those measures of moderation in living which tend to decrease the physiologic and psychologic stimuli that might produce a rise in arterial pressure. Special emphasis may be given to the psychologic component. Parallel with the physiologist's studies of hypertension and similar substances has moved the psychologic analysis of the hypertensive individual. And in certain respects it is more fruitful for the contemporary clinician to use the suggestions of the psychiatrists than those of the physiologists. The sympathetic and scientific management of a patient's emotional problems

may play a real role in inhibiting the progress of the disease as well as in keeping the blood pressure at lower levels. On the other hand, an attempt to depress arterial tension by the use of hormones, tissue extracts, electrical treatments, or various drugs (other than sedatives) has been either unsuccessful or of unproved value. Some substances of varying toxicity are in this unproved group. They have no place outside of the experimental clinic. In brief, it seems apparent that our ignorance of the basic mechanisms producing hypertensive vascular disease in man leaves us with no satisfactory direct therapy except in so far as an understanding of the emotional problems permits us to reduce adverse nervous influences. I recognize that some psychiatrists feel that there is a specific pattern of emotional disturbance at the root of essential hypertension. Here again, the internist is in no position to make flat denial, but at the present time he cannot find practical assistance from this hypothesis.

If we are unable to cure the disease itself, can we perhaps help these patients to avoid the complications, cardiac, renal, and cerebral, that are so characteristic? An immediate negative reply on the renal and cerebral side will be given by the medical man. On the other hand, it is possible to give sound advice in the prevention or at least postponement of cardiac failure, and, fortunately, many more hypertensives tend to follow the cardiac than the cerebral or renal routes. Reduction in weight, careful watch over the cardiac area, with exercise restrictions adapted to evidences of a changing myocardial status, avoidance of peak loads are general principles known to all, and in most instances are productive of real benefit. When failure of the left ventricle of the heart finally appears, the hypertensive heart usually yields well to modern cardiac management, and often many years of not too limited activity may ensue.

After pointing out the meager therapeutic possibilities in dealing with the causes of this disease, one may turn next to the treatment of symptoms. It is, first of all, necessary to differentiate between the clinical manifestations

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944. Part of a symposium on essential hypertension.

From the Department of Medicine, College of Physicians and Surgeons, Columbia University, and Presbyterian Hospital, New York City.

of uncomplicated hypertensive vascular disease and the complaints offered by these patients as complications appear. Thus, the symptoms of cardiac failure need no comment here, for they are handled as other cardiac conditions are; similarly, the terminal uremic state of nephrosclerosis is treated simply as uremia. It would be irrelevant to elaborate the details of such treatment in a paper on the care of essential hypertension. Furthermore, in ordinary general practice a majority of all individuals with high blood pressure belongs to the group without serious complications.

When considering the symptoms of essential hypertension per se, a curious problem arises. This problem is the difficulty in defining these symptoms. Because of the ease and objectivity of a blood pressure determination, variations from the normal range in both directions came to be an easy explanation of that large series of ill-defined complaints that are usually the expression of emotional disturbances. It is easier to tell an individual that he has a low blood pressure or a high blood pressure than patiently to seek out the worries and stresses of his life. It is not surprising, therefore, that an identical set of symptoms has been attached to both hypotension and hypertension. Exhaustion, lack of energy, dizziness, headache, easy fatigue, irritability, insomnia, are a few examples from this group of complaints. The low blood pressure syndrome is being rapidly discarded, but many patients are treated for hypertension when their symptoms could be relieved by attention to their anxieties or resolution of their conflicts. Indeed, this approach would probably benefit the hypertension itself. It must be confessed that the anxieties of the hypertensive patient are occasionally caused by the contagious panic of the physician as he reads the blood-pressure apparatus. I have recently seen a dramatic example of this. An entirely symptomless woman visited her physician for a routine check-up; he found hypertension, put her to bed for one month, and restricted her activities thereafter to a painful minimum. When seen eight months later, she had a long list of unpleasant feelings, every one classically neurotic. Stopping her complicated medication, reassuring her, and returning some interest to her life did not cure her hypertension but it removed her from the invalid list.

Although most complaints of exhaustion in patients with hypertensive vascular disease are difficult to differentiate from similar complaints in normal individuals, there are occasional instances of this manifestation in hypertension that correlate well with the advance of the disease and are clearly independent of any other life factors. No medical treatment other than rest is

helpful, and, in general, the symptom is a rather bad prognostic sign.

The symptom most commonly mentioned in relation to hypertensive vascular disease is headache. When one realizes the frequency of this complaint in normal people, it is apparent that a very careful analysis of other factors must be made before the hypertension itself can be conclusively implicated. In order to throw some light on the incidence of headache in this disease four of our medical students analyzed the headaches occurring in 144 cases: 33 general hospital patients, followed for ten years or more, and 111 cases from our hypertension clinic, with an average observation period of nine and a half years. The headaches were designated 1 plus to 4 plus according to their intensity. With these standards a 1 plus headache is so mild that it can be classified as no headache as far as this study is concerned. Our hypertensive patients had surprisingly few headaches; in fact, 38 per cent of them had no headaches on any visit. The clinic patients visited the hospital at least once a year, reporting on the previous twelve months' manifestations; the general medical patients came less frequently, but the entire group, over an average observation period of eleven years, accumulated 1,103 yearly visits. Since each visit included careful questioning as to an entire year, the fact that on 77 per cent of the visits no headaches were reported affords further evidence of their infrequency. On only 11 visits, or 1 per cent, were 4 plus headaches mentioned. Further analysis showed no correlation between changes in the level of the blood pressure and alterations in the severity of headaches; just as many headaches improved as the tension increased as when it dropped. In this small but carefully studied series there was also no correlation between the severity of headaches and the cardiac or renal status; nor did individuals who suffered cerebral accidents or progressive fundus changes present this symptom more often. Finally, it is of interest that of 89 cases with 2 plus or greater headaches, only 22 reported them on more than two consecutive yearly visits, only 8 on five or more consecutive years (one of these 8 was a typical neurosis). This lack of persistence in the headaches was not dependent on any specific therapy directed toward the hypertensive state. To summarize, a study of 144 patients, followed over an average of eleven years, showed that many hypertensives had no headaches, and very few of them had prolonged or persistently severe ones.

Headaches in hypertensive vascular disease should, therefore, be investigated with an open mind as to origin. The usual causes of headache should be considered and eliminated when-

ever possible. In those instances in which the hypertension seems to be the essential factor, one tries a series of experimental therapies, although it is hard to evaluate treatment because of the fact that spontaneous remissions are so frequently observed. Rest and sedation come first, with chloral as a most satisfactory remedy; if these fail and the headaches are very severe, lumbar puncture is very occasionally helpful. I am entirely unconvinced as to the beneficial influence of vasodepressor medications, such as the nitrites.

The foregoing discussion undoubtedly leaves the impression that I consider the average patient with uncomplicated hypertensive vascular disease to be a relatively symptomless and healthy person. This is true. Those hypertensive individuals who are genuinely sick fall into two classes: first, those with complications; and, second, a small group with rapidly progressive cases who, even before they exhibit cardiac, renal, or cerebral manifestations, become ill of headaches, exhaustion, anorexia, and irritability. This latter group tends eventually to develop nephrosclerosis and enter the so-called "malignant" phase. I know of no medical therapy that can interrupt their progress, and palliation is difficult. These individuals are entitled to surgical consideration even if the percentage of successes be low.

Fortunately, however, most patients with essential hypertension are relatively normal people and require only a minimal amount of management. While they should be examined at approximately yearly intervals in order to discover any signs of the usual complications, at other times they should be left entirely to their own devices. Weekly or monthly blood pressure measurements are not only unnecessary but actually detrimental.

The first step in treating a patient with uncomplicated essential hypertension consists in imparting to him the knowledge of its existence. It is difficult to exaggerate the importance of this initial move. In fact, I do not hesitate to say that when this step is properly planned the rest of the program could almost be omitted, but if it be poorly done, no amount of good advice can compensate. The current naive apprehension concerning high blood pressure, based on the belief that an immediate stroke will result from the blowing-out of an artery, tempts one not to divulge the existence of hypertension. There are two reasons for avoiding this easier path: first, to avert the possibility that someone else may take the blood pressure and create alarm; and second, to obtain the leverage that this knowledge affords in influencing the patient to carry out the therapeutic program. It is necessary at

this point to interject a few don'ts. Do not express anxiety. Do not reveal the exact blood pressure reading. Do not *immediately* interrupt the patient's career in any way. Do not take the cowardly course of mentioning every serious possibility, remote though it may be, merely to be on record against the event.

Every effort should be exerted to introduce a casual tone, and the average prognosis justifies it. It is reassuring to speak of a blood pressure "tendency," disabusing the patient at once of any alarming ideas that he has picked up from friends or physicians. It is comforting, and correct, to indicate that no alteration of life is necessary other than that which is wise for anyone of his own age, provided he be over 45 years old. The elevated blood pressure simply makes sensible behavior mandatory. Patients under 45 may follow the pattern of their more phlegmatic and slow-moving friends. No uncomplicated hypertensive should be given therapeutic limitations which would make his habits of life obviously unnatural.

It is hardly necessary to state in detail the directions required for sensible behavior. They include the avoidance of peak loads of exercise and undue pressure of work, but the program should never be a stereotyped one distributed on a printed sheet. As long a period as present-day schedules permit should be devoted to a sympathetic conference with the patient about his work, his habits, his stresses, and his worries. An appropriate therapeutic plan can be derived from the facts obtained in this interview. The hypertensive individual should be encouraged to return from time to time for reassurance and guidance. Do not use the blood pressure apparatus on these return visits, even if so requested by the patient. That apparatus should not appear oftener than once a year. I surely do not need to add that the appearance of any new symptoms or signs demands a careful total reappraisal, of which the height of the blood pressure should be considered as only an incidental item.

No specific dietary therapy has stood the test of clinical study. Meat and salt are permitted; nothing is forbidden except intemperance. However, many patients do require caloric restriction as an antiobesity measure, for there is no doubt that obesity is a serious detriment to the hypertensive. It is the opinion of some, in which I concur, that the use of tobacco is inadvisable in a disease that tends to develop vascular lesions; on the other hand, it is generally conceded that the moderate use of alcohol is harmless.

In turning to a discussion of drugs, one can give immediate approval to the use of sedatives. However, their use should be guided by the clinical needs of the patient, not by the existence

or height of the hypertension. It is fair to add that one is more sensitive to these clinical needs in a hypertensive than in certain other types of disease. I have previously indicated little enthusiasm for the vasodepressor drugs; moreover, it is psychologically bad practice to give a medicine to "bring the blood pressure down." This recommendation introduces an emphasis on the tension itself which it is wiser to avoid. In our clinic we have never used potassium thiocyanate because we felt that the reported results did not justify the experiment.

While the surgical treatment of hypertensive vascular disease is to be covered in a subsequent paper, it may be permissible for the internist to make a few comments. As I have stated previously, the individual with any evidence of impending nephrosclerosis has, in the immediate future, so serious a prognosis that he should not be denied operation, even though the statistical odds are greatly against him. Similarly, but slightly less emphatically, one can maintain that cardiac insufficiency or severe retinal damage, particularly papilledema, calls for a surgical attempt to avert their progress, if possible; again, regardless of the percentage of successes. Even the otherwise uncomplicated hypertensive who has had a cerebral accident may acceptably be included in the operative group in the hope of preventing a recurrence. The experiment should probably be made.

On the other hand, many internists find it extremely difficult to arrive at a satisfactory position regarding sympathectomy as a procedure to be employed in the average patient with essential hypertension who is symptom-free and entirely without complications. Here the good prognosis not only for survival but for continued health may be indefinitely prolonged. With each advancing decade of life, this prognosis is so considerably improved that in a patient over the age of 60 one would hesitate to open the subject of

operation at all. It will take some years of careful and continued observation before we can determine the value of sympathectomy as a preventive measure, to be carried out before definite changes in the heart, kidneys, or eyes take place. The previous discussion of symptoms not caused by complications would suggest the need for a certain amount of conservatism toward the use of radical surgery for this objective alone.

I would like to interject at this point a few comments on the classification of patients with hypertensive vascular disease by their fundus changes into the so-called groups I to IV. It is my opinion that this is an unjustified oversimplification which makes it difficult for the experienced clinician to analyze many of the published studies. This is particularly true when such a limited classification is adopted in reporting the results of sympathectomy. Hypertensive patients should be more or less quantitatively appraised in relation to their several components: cardiac, renal, cerebral, fundi, age, etc., the summation of which determines the status of the particular individual under consideration. Only the presentation of data based on this more comprehensive classification of patients will make it possible for the internist to reach sound conclusions as to the value of sympathectomy.

It has been my purpose in this paper to indicate that the average person with uncomplicated hypertensive vascular disease is relatively normal. He should be guided by his physician in the minimal revision of his life which his age and habits would suggest, bearing in mind that the common physical hazard is in the cardiac area. The adverse influence of emotional stress should be palliated by giving regular reassurance and by offering understanding aid with any emotional problems. The physician will thereby have accomplished all that lies within his power to make the fairly long span of most hypertensive patients as useful and as happy as possible.

## OBSERVATIONS ON CERTAIN LESS WELL-ESTABLISHED INVESTIGATIONS ON HYPERTENSION

IRVINE H. PAGE, M.D., Indianapolis, Indiana

**M**Y PREDECESSORS on this program, fortunately for me, have covered much of the information that rightly should be presented before any symposium on arterial hypertension. This, in a sense, leaves me free to dis-

cuss several miscellaneous and less well-established investigations which do not fit easily into a more formal presentation of the subject. I shall take fullest advantage of this opportunity.

### Classification of Hypertension

Arterial hypertension occurs in association with a wide variety of diseases. I have compiled a table of these, including all of them of which

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944. Part of a symposium on essential hypertension.

From the Lilly Laboratory for Clinical Research, Indianapolis City Hospital, Indianapolis, Indiana.

TABLE 2.—KEITH-WAGENER GRADING OF HYPERTENSIVES

Renal

A. Affections of vessels  
Arteriosclerosis  
Panarteritis nodosa  
Arteritis

ysm, arteriosclerosis,

B.

Infarcta  
Tumors  
Hypernephroma  
Ectopia  
Toxemia of pregnancy  
X-ray lesions  
Renal stones  
Hypogenesis  
Dystopia

C. Affections of perinephric structures  
Perinephritis  
Tumors  
Hematoma  
Wilm's tumors  
Retroperitoneal masses causing pressure on parenchyma

D. Affections of ureter  
Obstruction (pelvis, ureter, prostate, urethra)  
Pyelitis

Cerebral

Increased intracranial pressure (trauma, tumor, inflammation)  
Diencephalic stimulation  
Anxiety states  
Lesions of brain stem (ascending paralysis, poliomyelitis)

Cardiovascular

Heart failure  
Arteriovenous fistulae  
Angina pectoris  
Heart block  
Coarctation of aorta  
Atheromatosis  
Lead poisoning?  
Polycythemia

Endocrine

Pheochromocytoma  
Adrenal carcinoma  
Adrenal hyperplasia?  
Chromonephelioma  
Adrenal-like ovarian tumor  
Cushing's syndrome (pituitary adenoma)  
Pituitary basophilism?  
Acromegaly  
Thymic carcinoma  
Hyperthyroidism  
Arrhenoblastoma

Unknown

Essential hypertension  
Malignant hypertension

Group 1	Mild narrowing and sclerosis of the retinal arterioles. Compatible with good health for many years.
Group 2	Changes in retinal vessels more marked. Disease
Group 3	A <sub>1</sub> " " "
Group 4	Edema of the disk, diffuse retinitis, spastic and organic arterolar narrowing. Asthenia, loss of weight, headache, visceral disturbance, dyspnea, proteinuria, hematuria.

It will be noted that the grading depends chiefly on the state of the eyegrounds. If one is forced to pick a single examination from all the rest, surely no wiser choice could be made. The method obviously lacks precision, but for bedside management it has much to recommend it.

The most serious objection seems to be the dividing line between Groups 3 and 4. It appears to rest too heavily on the presence or absence of edema of the disks. Except in older people, hemorrhages and exudates of any marked degree seldom occur without being shortly followed by papilledema. We think that when hemorrhages and exudates occur the disease is serious and is only somewhat more serious when papilledema occurs.

In our own clinic we grade the severity of the disease not only by examination of the eyegrounds but from renal functional and cardiac studies. Especially do we find the so-called diodrast Tm—i.e., the maximal ability of renal tubular cells to secrete diodrast, which is a measure of tubular secretory capacity—a datum of the greatest importance.

Perhaps at this point I might say something about renal functional examinations in general. As clinicians, we have become so accustomed to the extremely simple tests, such as boiling urine, sediment examination, and dye estimation of secretory capacity that any examinations more complicated than these seem insurmountably difficult. Actually, even the most complete examinations, such as measurement of renal blood flow and tubular secretory capacity, are not nearly so difficult technically as many examinations on other organs which are commonly in use. When one reflects that the information obtained from a thorough study of the functions of the kidneys is of paramount importance in many

am aware (Table 1). Such tables are useful largely for two reasons. They point out the wide variety of morbid states in which hypertension may be anticipated and they act as a check list in establishing causative diagnoses. There is one unfortunate thing about this table; it accounts for, at most, only 3 to 5 per cent of the patients with hypertension. The remainder are the *essential and malignant* hypertensives. Can these similarly be classified into causative groups? The attempt has been made, but to date has achieved no signal success.

Keith and Wagener were the first to use a method of grading hypertensives according to the severity of the disease. Thinking about this

cardiovascular diseases, it is certainly not too much to ask that the simple give way to the more difficult but infinitely more informative procedures.

It has always seemed desirable to attempt a causative classification even though the data on which to make it are meager. It was obvious to most clinicians that many early or moderate hypertensives exhibited signs and symptoms of nervous hyperactivity and this led to the view that hypertension was caused by excessive vasomotor impulses producing increased peripheral resistance and hypertension. Certainly this is not wholly true, but equally certainly it is not wholly wrong.

It seems reasonable to believe that the hypertension of certain patients is, in large measure, caused by nervous hyperactivity, while in others a humoral mechanism is largely responsible. Indeed, it may well be that a neurogenic phase precedes the humoral and that the two imperceptibly shade into one another.

It is these early cases of hypertension, so commonly discovered at present, that will now be considered. We find it convenient to divide them into four groups in an effort to arrive at a useful diagnosis.

### Early Hypertension

1. Simple vasomotor lability—those who have transient and irregular episodes of elevated arterial pressure, chiefly systolic, associated with increased heart rate and usually some obvious emotional stimulus. The characteristic clinical picture of essential hypertension is not present. The latter does not necessarily develop.

2. Prehypertensives—those who will develop hypertension.

3. "Neurogenic" hypertensives—those with established hypertension but on a "neurogenic" basis—i.e., with signs and symptoms of nervous hyperactivity. Excessive vasoconstriction in the kidneys, if present, may be abolished by spinal anesthesia.

4. Early essential hypertensives—those who have established hypertension chiefly on a humoral basis.

*Prehypertensives.*—It is salutary to recognize that we know little about methods of differentiating prehypertension from simple vasomotor lability. And it is important to recognize that there may be a difference. It is no uncommon experience to find the arterial pressure at slightly abnormal levels in some people and ten years later find it at normal levels. Undoubtedly it is, however, more common to find it at a higher level than it was on the initial examination. The problem is how to differentiate the two. At present there is no sure way.

The response to the cold-pressor test may be, and usually is, more intense in the prehypertensive, especially the rise in diastolic pressure. But the difference may be insufficient for differentiation. A history showing a large incidence of hypertension in the family strengthens the diagnosis of prehypertension. Body build may give some slight clue. The psychologic inventory should be of value, but as yet there is no agreement as to what constitutes a pattern leading to hypertension. This lack is greatly in need of remedy. It is important at this stage to exclude other causes of hypertension, such as chronic pyelonephritis.

While all of these factors are of value in selecting the prehypertensives, still they are not sure enough. The addition of a few more definitive examinations would significantly increase the certainty of diagnosis. This is one of the important and persistent problems of cardiovascular disease.

*Neurogenic Hypertensives.*—Symptoms and signs of a disordered nervous system in certain hypertensives long ago led to the belief that in some, at least, the disease was caused by increased activity of vasomotor nerves. But objective evidence was not obtained that this was so. Indeed, so extravagant and uncritical were some authors in their assumption of the correctness of this view that a reaction against it was initiated, culminating in the belief that the nervous system had nothing whatever to do with hypertension. The swing is now again in favor of its importance in the genesis of certain cases of hypertension.

It is well to remember that the term "neurogenic" signifies that the hypertension has its origin in the nervous system probably by increasing the number of impulses carried by the vasomotor nerves. Strict proof that hypertension is ever so caused is not at hand. But certain scanty evidence suggests that it might be true.

It is possible that the neurogenic element reaches its zenith in the early phase of hypertension, to be supplanted later by the humoral mechanism. An example of the possibility of a neurogenic origin of hypertension is that found in only one of two identical twins. It is generally assumed that the hereditary pattern of identical twins is alike and hence the presence of a disease in one but not in the other tends to minimize the importance of the hereditary component. Renal blood flow and glomerular filtration rates are similar in the hypertensive and normotensive twins, but the psychologic patterns are different. From these facts it is suggested that the psychologic pattern is of primary causative significance.

From bedside observation, two clinical pictures have been observed which strongly suggest the

importance of the participation of the nervous system in certain types of hypertension. The first of these, hypertension with manifestations of a neurosis, is probably the most common, but also the less well defined. A small group of psychiatrists have attempted to find a characteristic psychiatric pattern which might have a causative connection with the hypertension, but as yet their results do not carry conviction. And still one has the feeling that there must be some common denominator in the mental pattern so frequently seen in hypertensives. It is a new vista and requires intensive investigation as a combined study by internists and psychiatrists. The second, the "hypertensive diencephalic syndrome," presents a clearly defined clinical picture, but the evidence in favor of its being of neurogenic origin is only by analogy. Regardless of its mechanism, it is important to differentiate it clinically because of its different course and prognosis.

*The Hypertensive Diencephalic Syndrome.*—This syndrome was described as occurring usually in young and middle-aged women, though it may be seen occasionally in men. It is characterized by hypertension of the labile sort, but especially by the periodic appearance of a blotchy blush which extends down over the face and upper chest, seldom, if ever, involving the limbs. Indeed, the latter are usually cold and have a dusky, mottled hue. Over the area of blush are minute beads of perspiration. Lacrimation or merely "watering" of the eyes may occur without an associated emotional counterpart. Tachycardia and hyperperistalsis are common. These episodes may occur without any apparent reason or may be brought on by embarrassment or excitement. The diagnosis of Grave's disease is often made because of these signs and symptoms and because the thyroid gland may exhibit slight diffuse enlargement and the basal metabolic rate may be elevated from +10 to +30. Subtotal thyroidectomy is of no benefit to these patients, yet it is the rare patient with this syndrome who escapes this operation.

The syndrome was called "diencephalic" because almost identical signs can be brought on by diffuse stimulation of the diencephalon in humans.

This syndrome is worth recognizing, not only because an operation on the thyroid gland may be avoided, but because the prognosis seems to be, on the whole, better than the more usual varieties of essential hypertension.

#### Renal Function Study Designed to Differentiate Vasoconstriction of Neurogenic and Humoral Origin

Studies employing the inulin and diodrast clearances along with examination of the maxi-

mal ability to secrete diodrast iodine—i.e., total effective tubular mass (diodrast Tm)—by Drs. A. C. Corcoran and R. D. Taylor show that patients denominated as hypertensives of "neurogenic" origin show little abnormality of renal function. If the vasoconstriction in them is of nervous origin and is not humoral, then it should be possible to release it by functional renal denervation such as that caused by high spinal anesthesia. Evidence that this has occurred should be obtained from examination of the changing balance between arterial pressure and renal blood flow.

It appears from a study of ten "neurogenic" hypertensives that this is so. When spinal anesthesia was administered so that it extended to the nipple line in patients with essential hypertension, no consistent change in arterial pressure or renal blood flow occurred, suggesting the humoral origin of the changed intrarenal hemodynamics. On the contrary, in the "neurogenic" group arterial blood pressure fell, renal blood flow rose, and resistance to the flow of blood in the kidneys fell sharply.

These findings suggest but by no means prove that neurogenic vasoconstriction occurs in certain patients with hypertension and points to a method for differentiating them from those with hypertension maintained on a humoral basis. Possibly the method may be of value in the selection of patients for thoracolumbar sympathectomy.

#### A Biologic Test Presumably Indicative of the Participation of the Humoral Mechanism in the Genesis of Hypertension

Several years ago we showed that if heparinized plasma from hypertensive dogs or human beings was perfused through a rabbit's ear vessels, with Ringer's solution as the perfusing medium, little or no vasoconstriction occurred. But if, instead of Ringer's solution, normal plasma was used to perfuse the ear, injection of hypertensive's plasma caused marked vasoconstriction, while normotensive's plasma did not.

The biologic test preparation used to demonstrate this phenomenon is an interesting one. The ear of a rabbit is severed with one quick stroke of a razor blade and a glass cannula is inserted into the auricular artery. The ear is then mounted on a plate in a temperature-regulated box and by means of a pulsating column of fluid, it is perfused. The drops coming from the ear are recorded by a drop-counter on a smoked drum. Both the length of time vasoconstriction persists and the intensity are noted.

We now employ carefully citrated plasma drawn so as to avoid hemolysis and coagulation. When blood coagulates, a vasoconstrictor is

TABLE 3.—EXAMPLE OF THE TEST FOR P.V.C.—RABBIT'S EAR PERFUSED WITH NORMAL CITRATED DOG'S PLASMA

formed regardless of the origin of the blood. Citrated plasma is also used as the perfusing medium. Only 0.2 cc. of plasma is required for a single test.

Vasoconstrictor substance resulting from mishandling the blood or by coagulation is easily detected when the plasma is perfused with Ringer's solution as perfusing medium, since neither hypertensives' nor normotensives' plasma causes significant vasoconstriction under these circumstances. Under the conditions of our test, plasma should either cause no vasoconstriction if used with Ringer's solution, or, at most, vasoconstriction lasting 1 1/2 minutes and reduction of 20 per cent of the initial flow.

When plasma is employed as perfusing medium, no more vasoconstriction should result when the test plasma is from a normotensive than occurs when Ringer's solution is used. But hypertensive plasma causes constriction lasting three to four minutes with 30 to 60 per cent reduction of the initial flow. The values shown in Table 3 will, I hope, make this clear.

I would not want to leave the impression that this test is very simple technically. It is tricky until one achieves considerable skill in performing the necessary manipulations. But once this skill is attained, the results are, for the most part, reliable. In a recent series of "blind tests," two mistakes were made in the examination of forty blood samples. And most of these were not run in duplicate, as of course they should be for reliability.

The significance of the results is not easy to evaluate. But since in this discussion I am not trying to stick too closely to established fact, an attempt can be made to see what they mean. We shall call the substance in the hypertensive's plasma "peripheral vasoconstrictor substance" or, more simply, P.V.C., to avoid, if this is possible, too broad implications resulting from a more

definitive name. This is certainly a nondescript nomenclature, but pending the chemical separation and identification, it seems better to postpone more exact wording.

Has P.V.C. anything to do with hypertension, and, if so, where does it come from? The answer to the first question comes very simply from the fact that P.V.C. occurs only in hypertensives, human or canine, so far as we have been able to determine. It is possible that there may be clinical states in which the hypertension is not actually manifest, but in which, despite this, the stimulus is there. So without more evidence we cannot say that it *never* occurs in the absence of hypertension, but so far it seems closely associated with it, and this applies to dogs with experimental renal hypertension or to human beings with hypertension of the essential, malignant, pyelo- or glomerulonephritic varieties.

Another reason we think it is of renal origin is that it occurs in the blood after a Goldblatt clamp is put on the renal artery or after the kidneys are wrapped in cellophane or silk. Adrenalectomy does not prevent its appearance. In human beings it occurs after a wide variety of renal injury with hypertension. Thus the most reasonable assumption is that P.V.C. results from the action of a renal mechanism set off by injury of various sorts.

The question arises whether P.V.C. is angiotonin or not. A number of observations indicate that it is not identical with angiotonin but is similar. It does not pass through an ultrafilter; hence we may assume that it is of high molecular weight or associated with high molecular-weight substances. It is unstable to heat but persists in plasma kept in an icebox or at room temperature for some time. In short, there are a number of chemical and physical properties which differentiate it from angiotonin, yet both substances appear to arise in much the same way. We make the tentative suggestion that P.V.C. is really angiotonin or some similar substance combined with a protein carrier.

Thus we arrive at the notion that when the renal humoral mechanism is set going, this protein vasoconstrictor is formed, which is reflected in the perfused rabbit's-ear test. As you probably have suspected by now, we are of the opinion that much clinical hypertension has a neurogenic stage and that it ultimately becomes humoral. Certainly what passes for neurogenic hypertension as determined by the spinal anesthesia test is a far less aggressive and mortal disease than the varieties we think of as being humoral in origin.

Therefore, if all these assumptions are correct, and most probably they are not, it is the hope that determination of P.V.C. in the blood will give some indication of when the humoral mechanism

has come into action. This may be the turning point in the hypertensive's life as he passes from the easily reversible, labile state to one more fixed, more destructive, and one far more difficult to treat. In broader biologic terms, the sophisticated nervous control of the blood vessels gives precedence to the more primitive humoral control.

### Effect of Large Doses of Vitamin A Concentrate on Normal and Hypertensive Patients

Several years ago, it was reported by Govea-Pena and Villaverde that doses of the order of 100,000 to 200,000 units of vitamin A given initially, followed by a maintenance dose of half that amount, produce spectacular results in lowering the blood pressure of hypertensive patients. Unfortunately, the protocols were so limited that it was not possible to judge the adequacy of the work. Shortly after the appearance of their article, a wave of self-prescribed vitamin A administration swept this country. The most fabulous cures were reported to us by people of all walks of life. It seemed, according to these inexperienced observers, that the answer to the problem of hypertension was at hand.

Some evidence was soon reported in which it appeared that vitamin A-containing preparations were antipressor in dogs with experimental hypertension. It seemed that the antipressor effect was not due to the vitamin A itself but to some other substance contained in the concentrate. The antipressor action was not evident after administration of the provitamin, carotene.

Furthermore, it persisted after destruction of the vitamin A by irradiation. Some investigators, on the other hand, found large doses of vitamin A concentrates ineffective in lowering the blood pressure of experimentally hypertensive animals.

The arterial blood pressure of hypertensive rats has been reported to be lowered by vitamin A concentrates. Fish body and liver oils contain a substance which lowers blood pressure, the effectiveness of which is increased by oxidative procedures which destroy vitamin A. Thus, the evidence so far on experimental animals suggests that an antipressor substance may be contained in fish oils and vitamin A concentrates which is not vitamin A itself. The results have, to date been highly irregular and further chemical studies will be necessary before adequate evaluation of this associated substance can be made.

The clinical results on carefully controlled patients have been far from encouraging. In striking contrast to the word-of-mouth, lay observa-

tion of spectacular fall in blood pressure, these results show no significant effect on blood pressure during periods of high doses of vitamin A concentrate (i.e., 100,000 to 400,000 units daily) exhibited for periods up to a year. It is just possible that the concentrates by chance did not have enough of the associated antipressor factor to be effective, though one must admit this as being somewhat remote.

Thus, the evidence for depressor action of vitamin A in human beings and even in animals is far from being established. An associated substance which is depressor is a perfectly reasonable assumption and we look forward with interest to the results of the work which is now in progress.

An effect of large doses of vitamin A which was rather unexpected came to light as the indirect result of the interest in this substance in the treatment of hypertension. The interesting observation had been made that the vitamin increases urea clearance in man and inulin clearance (a measure of glomerular filtration) in normal and vitamin A-deficient dogs. This suggested that vitamin A caused renal vasodilatation.

When large doses of vitamin A (100,000 to 400,000 units daily) are administered to nephritic or hypertensive patients, often there is an increase in effective renal blood flow and glomerular filtration rate and less often an increase in tubular secretory capacity for diodrast. The increase in renal blood flow was usually associated with increased cardiac output, the result of tachycardia and not of increased stroke volume.

These effects would seem to be desirable ones, especially if they were maintained. In a few patients they appear to be, but in others, after a temporary rise, the effect is lost. Whether this is due to the progressive nature of the disease or simply to the fact that the stimulant is no longer effective cannot be said. Another difficulty is that all patients do not respond. More study may resolve this problem.

It is surprising that such large amounts of this vitamin seem to exert no deleterious effects. One patient received 400,000 units daily for ten months without any evident injury.

In a word, there are indications that vitamin A, or associated substances, produce in some patients with reduced renal efficiency beneficial effects, lasting in a few cases, but transient in most.

It is much too early even to suggest now the outcome of future investigation with this group of substances.

I have, I think, kept my word about presenting a heterogeneous and ill-established group of observations. My purpose in doing so was obviously to suggest some of the new vistas that are gradually being disclosed.

# OCULAR FUNDI IN ESSENTIAL HYPERTENSION, PRE- AND POSTOPERATIVE

HUGH S. McKEOWN, M.D.,\* New York City

**S**URGICAL treatment of essential hypertension currently is not advised without a routine exhaustive study of the eyegrounds; originally, however, many patients were operated on in the absence of adequate ophthalmoscopic criteria with regard to the probable clinical success of the procedure suggested. This has been emphasized by the report of Wagener, Cusick, and Craig, whose findings indicated in the main that the less severe the organic lesions in the retinal arterioles the greater percentage chance there was of a successful surgical result.

It is necessary, therefore, for the observer to be familiar not only with the later intraocular manifestations of advanced essential hypertensive disease but primarily to appreciate the significance of the earlier and milder retinal evidences of generalized abnormal vascular physiology. Numerous classifications accordingly have been offered by many observers but this, in itself, is tantamount to admission that none is satisfactory. The most useful, however, are those of Wagener and Keith, Gifford and his associates, and Clay and Baird, in the order named. The first two authors have achieved a categorical simplification through consideration of so-called "albuminuric retinitis" associated with hypertensive cardiovascular renal disease as essentially *angiospastic* in origin. Thus there is afforded a relatively more definite prognostic evaluation not only statistically but also in the individual case, and this finds expression particularly in the determination of which cases are most suitable for operation.

It becomes convenient, then, to consider essential hypertension ophthalmoscopically as diffuse arteriolar disease varying in severity, and the observed alterations may be graded accordingly as 1, 2, 3, and 4, or mild, moderate, marked, and severe, respectively. This system of grading is a very useful guide to whether the particular phase of the disease under observation is chronic, progressive, or retrogressive. Thus, those patients who exhibit only smooth, generalized retinal arteriolar narrowing (whether mild or severe) are classified in Group I while those with sclerosis (no matter of what degree) together with generalized narrowing or attenuation of caliber of the retinal arterioles are to be placed in Group II.

When angiospastic retinitis, consisting of cotton-wool exudates and rather superficial hemorrhages, ensues together with previously existing narrowing and sclerosis the patient is to be placed in Group III, while those who exhibit papilledema in addition to all of the foregoing must be classified as Group IV, or "malignant hypertension." When the angiospastic retinitis seen in the latter two groups is encountered in the absence of sclerosis of the retinal arterioles, it is necessary to determine ophthalmoscopically whether one is observing acute vasospastic disease (of which hypertensive toxemia of pregnancy is the most frequent and obvious example) or the terminal hypertensive phase of chronic glomerulonephritis. In the latter the pallid eyeground indicative of secondary anemia frequently is a helpful diagnostic aid. The average life expectancy of chronic glomerulonephritic patients exhibiting terminal retinitis is about four months.

Keith, Wagener, and Barker, with reference to essential hypertension, have stated: "The prognosis for cases of Group III and especially for cases of Group IV is very serious. Because many more males than females belong to these two groups, the death rate is much higher among males than among females. A death rate, within one year, of 35 per cent in cases of Group III, and 79 per cent in cases belonging to Group IV, is in distinct contrast with that of 10 to 12 per cent in Groups I and II. The mortality rate in cases of Group IV approaches that found in certain forms of cancer." They comment further: "... not all cases fall into one of the four groups mentioned. There are many patients who have this condition (hypertension) who have, in addition to arteriolar dysfunction, diffuse arteriosclerosis, more especially of the aorta and of the coronary and cerebral arteries. Atherosclerosis of these arteries may be the determining factor as to the course and prognosis. With more knowledge relative to the occurrence of atherosclerosis in such vital internal arteries and with the aid of more accurate diagnostic methods, these cases might be grouped in a much more satisfactory manner than is possible at present."

[In the presentation of this paper four slides were shown to demonstrate the differential diagnostic fundus characteristics of the four principal groups of essential hypertension. The slides were kodachrome photographs of patients.]

In the early period of the surgical treatment of hypertensive disease, many patients were oper-

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1944. Part of a symposium on essential hypertension.

From Columbia University, College of Physicians and Surgeons, and the Department of Ophthalmology, Presbyterian Hospital, New York City.

\*Deceased

ated upon indiscriminately and many failures resulted. A criterion for the selection of cases suitable for operation was established only after a great many follow-up reports were made. It soon became obvious that in some types of cases, more than in others, the patient responded to sympathectomy. By classifying the patients with reference to their suitability for operation and by proper selection of cases the percentage of successful results has been increased considerably.

It has been reported, following the study of the retinas of patients before and after operation, that the chance of a successful result diminishes definitely with an increase in the severity of the organic lesion in the retinal arterioles. That is, a lowering of the diastolic blood pressure may be expected in a large percentage of hypertensive patients whose retinal arterioles show only grade 1 or 1 to 2 sclerosis. It has been shown, very interestingly, that the probability of obtaining satisfactory results is less in individuals with post-spastic-type than in those with chronic-type sclerosis.

It will be recalled that the development of arteriolar sclerosis in primary hypertensive disease is an expression of protection on the part of the body, or organism, as a whole against the potential lethality of abnormal vasospastic activity. When this activity is low grade, although progressive and prolonged, sclerosis is distributed diffusely; when angiospasticity is severe and rapidly fulminating, sclerosis will ensue if death does not supervene, but here the sclerosis will be distributed irregularly, since there has been afforded no opportunity for the usual adjustment of compensatory organic changes. In other words, the more "benign" the hypertensive disease, the less striking will be the ophthalmoscopic picture, and, accordingly, the better the prognosis from the surgical standpoint.

Wagener, Cusick, and Craig, and Fralich and Peet point out that the presence of retinitis in itself does not constitute a contraindication to sur-

gical treatment. According to the classification of Keith, diffuse arteriolar disease with hypertension, Groups I and II includes those persons with vascular changes in the retina but without retinitis. Patients with retinitis are placed in Group III or IV. Group IV represents those individuals in whom an acute angiospastic retinitis and measurable papilledema are superimposed on definite, pre-existing sclerotic or structural changes in the retinal arterioles. Therefore, a Group III hypertensive patient presenting mild to moderate, grade 1 to 2 sclerosis may be benefited by surgery, whereas a Group II patient, with marked to severe 3 to 4 sclerosis in all probability is doomed to obtain no benefit from surgery.

[Kodachrome pictures of the fundi of eight patients were shown. The pictures were of patients before surgery, immediately following surgery, and of at least one year postoperative follow-up. They illustrated the physical pathologic changes that may be expected from surgery of the several different groups of essential hypertension.]

## Conclusion

1. A careful estimation of the grade of sclerotic changes in the retinal arterioles is of value in determining the suitability of individual patients for surgical treatment in hypertensive disease. The proportion of good results may be expected to diminish as the amount of arteriolosclerosis increases.

2. Improvement in retinal lesions occurs during the immediate postoperative period in a good percentage of cases. This improvement is confined to decrease in the degree or to disappearance of the retinitis or to lessening in the tonic or spastic constriction of the arterioles or both.

3. Improvement may not be expected in the sclerotic or structural lesions in the retinal arterioles. An increase in the grade of arteriolosclerosis has been observed in a few cases seen at varying periods following operation.

## THE SURGICAL TREATMENT OF HYPERTENSION\*

Some Circumstances Under Which Lumbodorsal Sympathectomy Appears to Be Inadvisable in Hypertensive Patients

R. H. SMITHWICK, M.D., Boston

FOR the past eleven years, a clinical investigation\* of hypertension in man has been in

Medical  
May 10,

Massachusetts General Hospital.

\* This investigation is being aided by a grant from the Proctor Fund, Harvard College.

progress at the Massachusetts General Hospital. Various departments—medical, pathologic, research, and surgical—have participated in this study.

A number of recent communications dealing with different aspects of this complicated problem have been written by White *et al.*,<sup>1-4</sup>

FIG. 1. Type 1 hypertension. A Group 1 result. Blood pressure (lying) 165/115 before and 109/56 one year after operation. A 27-year-old man, Grade 0 eyegrounds, normal cardiac and renal functions; response to sedation 104/70.

Castleman *et al.*,<sup>5,6</sup> Talbott *et al.*,<sup>7</sup> and Smithwick.<sup>8-10</sup>

Various operations were performed upon the sympathetic nervous system which were designed to interrupt the vasomotor supply to the arterioles of the abdominal (splanchnic) viscera. During the first five years, small groups of patients were operated upon by various technics, including multiple-stage operations in some cases. At the end of this time, it was felt that an operation could be performed which would result in physiologic evidence that this portion of the arteriolar bed has been thoroughly or completely sympathectomized. This evidence was the appearance of postural hypotension in the acutely denervated state. The technic for this procedure, which we have come to call lumbodorsal splanchnicectomy, was published in 1940.<sup>11</sup> It has been used continually for the past six years, since the latter part of 1938. In the first few years, it was employed in small groups of hypertensive patients, but more recently, during the past two years in particular, the series has been increased to over 500 cases.

The two stages of the operation are performed about ten days apart. The great splanchnic nerves are removed from the celiac ganglia to the midthoracic level and the sympathetic trunks are excised from at least the ninth dorsal to the first lumbar to at most the sixth dorsal to the third lumbar, inclusive. The operative mortality has been less than 3 per cent, which is low considering

the severity of the hypertensive disease in many of the cases. A further discussion of surgical technic will be published in the near future.

In recent publications,<sup>8-10</sup> it was noted that a significant and persistent lowering of the diastolic pressure followed operations of the above order of magnitude in the majority of a series of 156 cases. This was associated with favorable changes in eyegrounds, electrocardiograms, and cardiac and renal functions as judged by ordinary tests, as well as in symptoms. The lowering of blood pressure was thought to be due to a decrease in the tone of arteriolar smooth muscle. It was noted that the effect of operation in certain cases did not appear to be very significant, and in some cases the blood pressure when studied one to five years afterwards was found to be higher.

The results were divided into five groups. In the first four, the diastolic pressure was lowered 30 mm. or more, 20-29 mm., 10-19 mm., and up to 9 mm., respectively.

In the fifth group, the level was higher. It was also noted that, in general, women did better than men. Also, the results varied according to the type of hypertension. This refers to the width of the pulse pressure, which varies considerably in these patients. The cases were divided into three types: narrow, intermediate, and wide pulse pressure, and were called Types 1, 2, and 3, respectively. In general, it was found that the wider the pulse pressure the higher the percentage of poorer results.

FIG 2 Type 1 hypertension. A Group 2 result. Blood pressure (lying) 150/110 before and 118/87 one year after operation. A 30-year-old woman, Grade 1 eyeground changes, cardiac and renal functions normal, response to sedation 100/70.

The purpose of this communication is to discuss the results of a slightly larger series of 179 living patients, followed one to five years, who had elevation of the diastolic level to 100–170 mm before operation. In addition, the 36 known deaths which have occurred during the past six years will be reviewed. This makes a total of 215 cases.

It is advisable to perfect the selection of cases for surgical treatment as far as possible. The complexity of the hypertensive state in man, which appears to be the result of a number of different factors joining together in an infinite variety of combinations, makes it necessary to divide cases into many groups, holding constant as many of the various factors as possible. This requires a large series of cases and the data available at this time permit only a preliminary and tentative discussion of this matter. By dividing the 215 cases into groups according to the two sexes, the three types, and five levels of preoperative diastolic pressure, a total of thirty groups, it is possible to suggest four rules, which, had they been available at the beginning of this investigation and followed closely, would have been extremely helpful in reducing the total mortality and the number of poorer (Group 5) results. These four suggestions have been given considerable thought, as it is realized that it is just as important to be able to state that a hypertensive patient cannot be helped as to indicate that he can be benefited by a particular form of treatment. As our experience increases, these suggestions will

be modified, amplified, and corrected if found to be in error, with the ultimate goal in mind the ability to select only those patients who will derive worthwhile results from operation.

Furthermore, during the past year in particular, we have operated upon a number of patients in the earlier stages of the hypertensive state, some with resting diastolic levels of 90–99 mm, and even a few who had levels below 90 when studied in the horizontal position after several days of rest and hospitalization, but who when up and active ordinarily had well-elevated levels, often severe, with associated cardiovascular changes. The follow-up of such cases may conceivably disclose that operation may be even more helpful when performed in the earliest instead of later stages of the disorder.

The preoperative data upon which the diastolic level and type of hypertension is based has been obtained in these cases as part of a routine of study. The patients have been hospitalized and the following studies carried out: fasting non-protein nitrogen, sugar, Hinton test, hematocrit, serum protein, cholesterol, hemoglobin, and smear. Description of eyegrounds with fully dilated pupils has been furnished by an ophthalmologist, and a 7-foot heart plate, electrocardiogram, and clinical evaluation of cardiac status have been made by an experienced cardiologist or internist. Several urinalyses, urine concentration test (twelve-hour), intravenous phenol-sulfonephthalein test (fifteen-, thirty-, and sixty-minute and two-hour), and intravenous pyelo-

FIG. 3. Type 1 hypertension. A Group 1 result. Blood pressure (lying) 183/130 before and 124/93 fifteen months after operation. A 52-year-old man, Grade 3 eyegrounds, normal cardiac and renal functions; response to sedation 128/90.

gram have been done. Admission blood pressure was taken by a physician and a four-hourly blood pressure chart kept by nurses.

A postural and cold blood-pressure test is performed. This test is employed to study the reactivity of the vascular bed and to determine the approximate severity and type of hypertension of the particular individual. It is best performed after two or three days of hospitalization, most of which time should be spent in bed. To perform this test it is desirable that the environment be quiet and that the patient be lying on a comfortable bed or couch. A special room is recommended so that ward conditions of study can be avoided. The patient should rest for fifteen to twenty minutes. Readings of pulse and blood pressure are taken every minute for five minutes, first with the patient lying and then with the patient sitting and then with the patient standing. The patient then lies down again and pulse and blood pressure are again taken every minute, for five minutes, following which the hand opposite the side on which the blood pressure is taken is placed in ice water (4-5 C.) up to the wrist for exactly one minute, readings of pulse and blood pressure being taken when it has been in the water for thirty seconds and again when the hand is removed at exactly the end of a minute. Following this, readings of pulse and blood pressure are taken every minute for an additional five min-

utes. The patient then assumes the standing position again and the cold test is repeated in the upright position exactly as it was performed in the horizontal position, five readings of pulse and blood pressure preceding and following the one-minute period of stimulation by cold. It is advisable to use a mercury manometer. The systolic level is the first audible sound, which is generally heard just above the level at which the radial pulse can first be felt to come through. The diastolic level is taken as the fading point just above the disappearing point. There is no objection to recording both diastolic levels. The readings may be taken by a physician, but preferably by a trained technician, in order to avoid the pressor effect of the presence of a physician. Every attempt is made to study the hypertensive state at its basal level.

A sedative test is performed as follows: After a light supper the patient is given 3 grains of sodium amytal p.o., at 7:00, 8:00, and 9:00 P.M. (a total of 9 grains) and an hourly blood-pressure and pulse chart is kept from 7:00 P.M. to 7:00 A.M., stating whether the patient is asleep, drowsy, or awake at each reading.

Following operation, many of these tests have been repeated, first at the end of one year, and at annual or biennial periods thereafter. It was originally intended that the patients be rehospitalized for postoperative study. However, the

FIG 4 Type 2 hypertension. A Group 1 result. Blood pressure (lying) 167/102 before and 97/69 nineteen months after operation. A 32-year-old woman, Grade 4 eyegrounds, normal cardiac function, and slight impairment of renal function, response to sedation 120/90.

shortage of beds resulting from the war has made it necessary to study the cases in an ambulatory fashion. Consequently, the postural and cold blood-pressure test has been repeated fifteen to twenty minutes after entrance to the hospital. The postoperative blood pressure data are therefore not strictly comparable to the preoperative. Other blood-pressure data are available, but none obtained in as near a standard and comparable fashion as this. Various illustrations of the postural and cold test before and after operation are shown in Figures 1-7.

The preoperative diastolic level is the average of the five readings in the resting horizontal position. The systolic level is the average of the five comparable readings. The pulse pressure is the difference between the two. The types are determined as follows. In Type 1, the pulse pressure is less than one half the diastolic pressure. In Type 2, the pulse pressure is equal to or up to 19 mm more than one half the diastolic level. In Type 3, the pulse pressure is 20 mm or more greater than one half the diastolic level. In Figs 1-7, the postoperative blood pressure data are cross hatched. The result of operation has been judged by the difference in the average of the five diastolic blood pressure readings in the first portion of the test, the lying level before and after operation.

In the rules to be suggested, some reference to eyeground changes is made. So far a very simple classification has been used which will be amplified later. Grade 0 eyes are normal and Grade 1

eyes have changes other than arteriovenous compression, hemorrhage, or exudate, or measurable elevation of the disks, or papilledema. Grade 2 eyes are those with arteriovenous compression but without hemorrhage, exudate, or papilledema. Patients with Grade 3 eyes have hemorrhages and/or exudate without papilledema. Grade 4 eyes have papilledema, generally with hemorrhage and/or exudate with any or all types of arterial change.

The 36 known deaths which have followed the surgical treatment of over 500 patients during the past six years have been divided into three groups—operative deaths, deaths within one year, and deaths over one year following operation. The number of cases in each group was approximately the same—13, 12, and 11, respectively. All but 4 were the result of complications of the disorder—cardiac, cerebral, or renal. All of the unrelated causes of death occurred in female patients, of which 2 were operative deaths due to pneumonia and bilateral pneumothorax, and 2 occurred within one year, because of meningitis and peritonitis. Of the 32 remaining deaths, 29 were in male patients and 3 in females, a striking sex predominance, particularly since female patients exceeded males in the series as a whole 56 per cent to 44 per cent.

Of the 179 living patients, the number of cases in each of the five groups of results as judged by the change in the diastolic pressure following operation was 75, 32, 35, 21, and 16, respectively.

FIG. 5. Type 2 hypertension. A Group 1 result. Blood pressure (lying) 190/116 before and 117/70 one year after operation. A 40-year-old woman, Grade 0 eyegrounds, normal cardiac and renal functions; response to sedation 130/90.

These results as well as the 36 deaths have been critically reviewed when divided into the previously mentioned thirty groups according to the two sexes, three types, and five levels of preoperative diastolic pressure. With reference to the latter, the five levels contain cases with preoperative diastolic pressures of 100–109, 110–119, 120–129, 130–139, and 140 and over, respectively. There are thus thirty possible combinations of type, sex, and diastolic blood pressure level. Examples of all of these exist except Type 3 men, 130–139, and type 3 men, 140 or over. The number of cases in each combination varies from 2 to 15. Such a division places the patients in roughly comparable groups for study. These, however, must eventually be further subdivided according to the many other variables such as age, the state of the brain, eyes, heart, and kidneys, as well as arteriolar disease as judged by biopsy material.

The cases in these thirty subdivisions have been studied with a view toward reducing the mortality and the Group 5 results in particular. It appears that most of the deaths and poorest results following lumbodorsal splanchnicectomy have occurred under certain circumstances. The most obvious of these are as follows and might be tentatively considered as contraindications to surgery:

1. In the presence of congestive heart failure and impaired kidney function as indicated by an elevated nonprotein nitrogen or a reduction in the

intravenous phenolsulfonephthalein output to below 15 per cent in the first fifteen minutes.

2. In male patients with resting diastolic levels of 140 or more, operation does not appear to be advisable unless there have been no cerebral vascular accidents or episodes of encephalopathy, and there is no evidence of actual or impending cardiac failure, and the kidney function is normal or near normal as indicated by an intravenous phenolsulfonephthalein output of 20 per cent or more in the first fifteen minutes.

3. In women patients with resting diastolic levels of 140 or more, the same rule as for men should be observed with the exception that operation may be performed in the presence of impaired renal function providing the intravenous phenolsulfonephthalein output is 10 per cent or more in the first fifteen minutes.

4. For patients with lower diastolic levels the following tentative suggestions are made:

- (a) Type 3 males with Grade 3 eyes, levels 100–109 and 110–119, have so far done poorly almost regardless of any other factor. The same applies to type 3 women with Grade 3 eyes, level 110–119, except those with a normal kidney function (phenolsulfonephthalein output of 25 per cent or more in the first fifteen minutes) and a good response to sedation (a diastolic fall to 90 or less).

- (b) Men and women with levels 100–109 and 110–119, of any type, ages 48–57, with previous

Rule 4	3	2	1	0
Rule 4	13	5	3	5
Number after applying rules	4	0	1	3

cerebral accidents and Grade 3 eyes and a poor response to sedation did poorly. Under the same conditions, those with lesser eyeground changes and congestive failure or poor kidney function (phenolsulfonephthalein output 10-15 per cent in fifteen minutes) also did poorly.

(c) Type 1 and 2 males, level 120-129, aged 38 or more, with Grade 3 and 4 eyeground changes, have not done well unless the kidney function was normal (phenolsulfonephthalein output of 25 per cent or more in fifteen minutes). Similar cases without retinitis or papilledema but with a marked reduction in kidney function (phenolsulfonephthalein output of 5-10 per cent in fifteen minutes) have not done well.

(d) Type 1 females, level 120-129, have so far done poorly when the diastolic level did not fall to 100 or less on sedation.

(e) Type 2 males, level 130-139, with Grade 4 eyes have done poorly when the kidney function was below 25 per cent in fifteen minutes.

(f) Of type 3 females, level 130-139—2 patients with Grade 3 eyes did poorly, one with normal kidney function and a poor response to sedation (see (a)); and the other with a previous cerebral accident and a poor response to sedation (see (b)).

The effect of these four rules upon the mortality and the results in the living patients, when applied to the 215 cases under discussion, is shown in Tables 1 and 2, respectively.

It should be noted that a marked reduction in the deaths and in the Group 5 results has occurred at the expense, however, of one Group 1 result and two Group 4 results. In all three instances, these particular cases have been clinically worth while. It would seem, however, that this is not too great a price to pay for the marked re-

TABLE 2.—RESULTS FOLLOWING LUMBODORSAL SPLANCHNICECTOMY

duction in total mortality and the poorer results. All of these rules should at this time be regarded as tentative suggestions to be amplified and modified as our experience increases. There still is considerable room for improvement so far as the accurate selection of patients for operation is concerned. These suggestions may, perhaps, be of some help to those who are concerned with the surgical approach to this complicated problem.

### Summary

Certain suggestions are made regarding the selection of hypertensive patients for surgical treatment. These are based upon a review of the data available concerning 215 patients who have been treated by lumbodorsal splanchnicectomy. These suggestions are directed primarily at reducing the mortality and the poorer results.

### CHURCHILL ON HEALING SCIENCE

The discoveries of healing science must be the inheritance of all.

That is clear. Disease must be attacked whether it occurs in the poorest or the richest man or woman, simply on the ground that it is the enemy; and it

must be attacked just in the same way as the fire brigade will give its full assistance to the humble cottage as readily as it will give it to the most important mansion.—Winston Churchill, *Lancet*, March 11, 1944

# BIOCHEMICAL FACTORS INFLUENCING WOUND HEALING

MAURICE BRUGER, M.D., New York City

ONLY within recent years have surgeons begun to appreciate the fact that the rate and efficacy of wound healing are dependent in no small measure upon several important biochemical factors. These may be tabulated as follows: (1) the ascorbic acid (vitamin C) content of the tissues, (2) the protein concentration of the serum, (3) carbohydrate metabolism, and, to a limited extent, (4) calcium and phosphorus metabolism (in the healing of fractures).

As far as is known at present, these four factors affect wound healing specifically, although it has been stated that the over-all picture may be modified by the general status of body nutrition and perhaps by vitamins other than ascorbic acid. There is little or no evidence that such is actually the case.<sup>1</sup> Poor body nutrition (and weight loss) will be reflected in depleted serum proteins and not infrequently in a decreased concentration of ascorbic acid in the tissues as well, thus influencing the processes of tissue repair.

The present discussion does not embrace local factors deterring the healing of wounds. It is obvious that imperfect suturing, activity on the part of the patient, coughing, straining, or rough handling on the part of attendants disturb the adherence of the wound edges. Moreover, excessive trauma, infection, strangulation of tissue, the presence of foreign bodies, and excessive tension are important local factors predisposing to poor wound healing.<sup>2</sup> We are concerned here with the less apparent though equally important general factors influencing tissue repair.

## Ascorbic Acid (Vitamin C)

Twenty-five years ago, it was observed that in scurvy the main primary deficiency was a lack of intracellular cement substance.<sup>3</sup> Since then, it has been demonstrated frequently that an adequate concentration of vitamin C in the tissues is a necessary prerequisite for normal wound healing, since this vitamin is essential for the maturation of procollagen to the collagen of fibrous tissue.<sup>4,5</sup> Apparently this vitamin is also essential in the healing of fractures, since the production of osteoblasts appears to be dependent upon the vitamin C content of the tissues.

In guinea pigs, wound healing is retarded when the animals are kept on a subscorvy diet. The tensile strength of wounds is about one half of

normal on the sixth postoperative day and about one quarter of normal from the eighth through the fourteenth days. The addition of high vitamin C dosage to the diet of such animals postoperatively permits the wounds to reach the same tensile strength by the eighth postoperative day.<sup>2</sup> In human subjects, it has been found that a sufficient depletion of vitamin C produces a decreased ascorbic acid content and tensile strength in healing wounds in the skin and fascia. A fasting plasma ascorbic acid level below 0.20 mg. per 100 cc. must be reached before these changes occur.<sup>6</sup>

Many chemical and biophysical procedures have been devised in order to evaluate vitamin C deficiency; these have recently been reviewed critically.<sup>7</sup> Three methods will be described briefly here: (1) the fasting vitamin C content of the plasma, (2) the vitamin C saturation test, and (3) the tourniquet test (Rumpel-Leede phenomenon).

The normal fasting vitamin C is stated to range from 0.7 to 1.4 mg. per 100 cc. of plasma. A deficiency in plasma vitamin C usually reflects an inadequate concentration of this vitamin in the tissues in spite of the fact that the dietary history may indicate an adequate consumption of citrus fruits. For reasons that are not as yet too clear, some persons either fail to absorb this vitamin from the gastrointestinal tract or are unable to store it in the tissues.

The vitamin C saturation test is a valid procedure, perhaps more so than the fasting ascorbic acid content of the blood, for gaging the tissue content of this vitamin. In this test, the patient voids and discards the urine, then 1 Gm. of ascorbic acid (dissolved in 10 cc. of saline or water) is injected intravenously and the urine is collected for exactly five hours after the injection. If the tissues contain adequate amounts of this vitamin, more than 450 mg. of ascorbic acid are excreted in the five-hour urine. Obviously, in persons with deficient stores of vitamin C, the greater part of the injected vitamin is absorbed by the tissues and decidedly less than 450 mg. are excreted in five hours.

The tourniquet test, unlike the two procedures described above, requires no chemical analyses. The test has recently been modified as follows:<sup>8</sup> a circle the size of a twenty-five-cent piece is drawn 4 cm. below the crease of the elbow on the inner aspect of the forearm. The blood-pressure manometer is then applied as usual upon the upper part of the arm and inflated to a pressure midway between the diastolic and systolic pres-

From the Department of Medicine, New York Post-Graduate Medical School and Hospital, Columbia University, New York City.

Presented before the Clinical Society of Reconstruction Hospital, New York City, December 15, 1943.

sure of the patient. This is maintained for fifteen minutes, after which the pressure is released; at the end of five minutes the number of petechiae within the circle is counted with the naked eye. A normal count is rarely above ten petechiae. In the presence of vitamin C deficiency the associated increased capillary fragility is reflected in high petechial counts. It should be noted that the tourniquet test will give false positive reactions in the blood dyscrasias—e.g., leukemia, polycythemia vera, thrombocytopenic purpura, etc. Again, negative results will be obtained in patients with vitamin C deficiency in the presence of moderate or severe anemia, primary or secondary.

Delayed or imperfect wound healing in the presence of ascorbic acid deficiency is best treated by the liberal use of crystalline vitamin C. This material may be administered intravenously in daily doses of  $\frac{1}{2}$  or 1 Gm. dissolved in a small volume (10 cc. or 15 cc.) of physiologic saline or distilled water or added to a glucose or glucose-saline infusion if such therapy is being used simultaneously. Vitamin C may be prescribed orally and, in most instances, this route is eminently satisfactory. Tablets of vitamin C containing 25, 50, or 100 mg. each of the crystalline material are obtainable. Three hundred to 500 mg. per day in divided doses may be ordered. Allergic reactions to ascorbic acid are rare; in fact, this vitamin has been used freely in the treatment of various types of hypersensitivity.

### Serum or Plasma Proteins

It is universally appreciated that protein is necessary for the growth and repair of tissues since, fundamentally, tissues are protein in structure. Unlike fat, the reserve store of protein in the body is relatively small (2 Kg.), the energy equivalent of which could supply the basal caloric requirements of the average adult for only five days.<sup>9</sup> Protein deficiency in blood and tissues will arise rather early, therefore, in conditions of protein starvation or inanition.

Tissue and plasma protein deficiency may occur even in the presence of adequate protein intake. The enzymatic hydrolysis of protein and the absorption of the amino acid end-products may be interfered with in patients with achylia gastrica, gastrectomy, jejunostomy, ileostomy, jejunocolic fistula, and diarrhea. In diseases of the liver, this organ may fail to synthesize protein from the amino acids brought to it by the portal vein (e.g., cirrhosis of the liver, hepatitis, chloroform poisoning, thyrotoxicosis, liver abscess, acute yellow atrophy of the liver). Again, protein may be lost in excessive amounts from the body (e.g., suppuration, burns, chronic loss of blood, helminthic infection, nephrosis, frequent

paracenteses, chronic bile peritonitis). The surgeon should remember that the amount of protein lost in pus may range from 8 to 21 Gm. per 100 cc.<sup>10,11</sup> It is obvious from what has been stated above, therefore, that hypoproteinemia may result from prehepatic, hepatic, or post-hepatic causes.<sup>12</sup>

Since plasma protein is in dynamic equilibrium with tissue protein, a deficiency of the former reflects a depletion of the latter. The total serum or plasma proteins vary normally from 6 to 8 Gm. per 100 cc., of which the albumin component ranges from 4 to 5 Gm. and the globulin from 2 to 3 Gm. per 100 cc. The albumin fraction is the important component, since its relatively smaller molecular size compared to the globulin is attended by greater osmotic pressure. This is important, since edema, which interferes appreciably with wound healing, is dependent in no small measure on the osmotic pressure exerted by the serum albumin. In fact, when the total serum protein falls to approximately 5.0 Gm. per 100 cc. or the serum albumin reaches 2.5 Gm. per 100 cc. edema is imminent.

In patients with hypoproteinemia, wound healing is slow and the tensile strength of the wound is decreased. It was shown twenty-five years ago that the latent period in wound healing, that is, the time from the injury up to the time of fibroblast proliferation, may be shortened almost to the point of elimination by a high protein diet.<sup>13</sup> More recently, it was demonstrated that the rate and degree of growth of fibroblasts in wounds may be increased by an augmented protein intake.<sup>14</sup> Still more recently, severe hypoproteinemia has been shown to retard the formation of bony callus in experimental fractures.<sup>15</sup>

Hypoproteinemia not only causes delayed and inadequate wound healing but may be attended by sudden disruption or dehiscence of wounds.<sup>16,17</sup> Recent studies have confirmed these observations, although it must be conceded that decreased serum protein by itself is neither a necessary nor sufficient cause for wound disruption in all cases.<sup>18</sup> Obviously, poor surgical technic and excessive intra-abdominal pressure from any cause would favor wound disruption even in the presence of normal serum proteins. It is of interest to note that wound disruption failed to occur in hypoproteinemic dogs treated postoperatively with lyophilized serum administered intravenously.<sup>19</sup>

Diminished serum proteins further result in delayed gastro-intestinal motility and may cause failure of function of surgical gastro-intestinal stomata.<sup>20</sup> Moreover, the accumulation of edema fluid in the walls of the gut which commonly occurs in nutritional deficiency states interferes with the "take" of the stoma.

Hypoproteinemia is best combated by a high protein diet (2 to 3 Gm. of protein per Kg. of body weight) provided, of course, that such diets can be administered and utilized. It has been calculated that 375 Gm. of protein are required each day for a period of ten days to elevate the serum protein level from 5 to 7 Gm per 100 cc.<sup>21</sup> Whenever possible, surgical patients should be prepared for operation by several days of optimum nutrition, including a well-balanced diet of high protein intake, of high caloric value, and of high vitamin content. It has been stressed that this period of preparation should begin at home ten to fourteen days before the operation.<sup>22</sup>

When the administration of a high protein diet is impossible for any reason or when emergency surgery must be performed in a hypoproteinemic patient, other means of protein administration must be resorted to. For this purpose, whole blood, plasma, or casein digests may be used.

The most efficiently utilized protein in the treatment of hypoproteinemia is plasma,<sup>23</sup> since homologous plasma protein apparently furnishes all the body needs for protein.<sup>24</sup> Two units of plasma (500 cc.) contain approximately 35 Gm. It is obvious that if the total body needs for protein were to be derived from plasma, whole blood, or serum, the cost of such therapy would be prohibitive. Moreover, there is some recent evidence to indicate that the injected plasma protein, especially when administered in large amounts, may not be retained permanently in the blood and tissues of the recipient;<sup>25</sup> this is a rather important finding and certainly requires confirmation.

In the present writer's opinion, casein digests offer a convenient and relatively inexpensive method of administering parenteral proteins. Such hydrolysates\* have been shown to maintain nitrogen equilibrium when injected intravenously<sup>26</sup> or subcutaneously.<sup>27</sup> Ascorbic acid should be given simultaneously, since it has been shown that this vitamin is essential for the proper metabolism of certain amino acids, namely, phenylalanine and tyrosine.<sup>28,29</sup>

The administration of 100 cc. of Stearn's Amino Acids will yield 15 Gm. of protein to the body provided, of course, that the amino acids are completely synthesized to protein by the liver. The contents of one or two bottles (100 cc. or 200 cc.) may be added to 500 cc. or 1,000 cc. of glucose, saline, or glucose-saline solutions and administered intravenously (the subcutaneous, intramuscular, and intrasternal routes may also be used). When parenteral feeding is the only means of sustenance, adequate amounts of carbohydrate must be given simultaneously for its protein-sparing action. It is obvious, therefore, that an infusion of 1,000 cc. containing 10 per

cent glucose and 30 Gm. of amino acids will yield 100 Gm. of glucose and 30 Gm. of protein. In order to offset possible reactions, such as flushing, nausea, vomiting, chills and fever, amino acids should not be administered intravenously too rapidly. Most postoperative patients are able to tolerate from 7½ to 15 Gm. per hour without difficulty.

In the average postoperative patient (without liver dystrophy or undue protein loss) nitrogen equilibrium can be attained by the administration of 1 to 1½ Gm. of protein per Kg. of body weight; a man weighing 150 pounds, therefore, can be kept in good protein nutrition by the administration of 500 cc. to 600 cc. of amino acids per day provided, of course, enough calories in the form of glucose are simultaneously fed or injected. The present writer has had no experience with aminogen; a competent observer has recently described his clinical observations with this material.<sup>30</sup>

### Carbohydrate Metabolism

It is generally appreciated that surgical wounds tend to heal slowly, inadequately, or not at all in patients with uncontrolled diabetes mellitus. The healing of abdominal incisions in dogs rendered diabetic by pancreatectomy has been studied. The repair of these wounds is abnormal compared to the behavior of identical wounds in healthy animals used as controls. Edema of the tissues, delayed and decreased deposits of fibrin, excessive cellular reaction, slow formation of new blood vessels, and frequent thromboses in preformed vessels were noted in the diabetic animals. Healing proceeded normally, however, when the diabetes was well controlled.<sup>31</sup>

The view has long been held that the hyperglycemia in the uncontrolled diabetic (and hence the increased concentration of sugar in the tissues) renders the individual more susceptible to infection. Bacteriologic studies have shown, however, that blood to which varying concentrations of sugar had been added proved to be no better a culture medium for staphylococci than blood without added sugar.<sup>32</sup> Hyperglycemia per se probably does not retard wound healing nor predispose to infection provided that (1) insulin is acting and the metabolism of the tissue cells is not disturbed;<sup>33</sup> (2) the peripheral circulation is adequate;<sup>34</sup> and (3) the resulting glycosuria and concomitant polyuria do not produce excessive dehydration.<sup>34</sup>

It has been observed, nevertheless, that delayed or imperfect wound healing may occur in apparently nondiabetic individuals who manifest a fasting hyperglycemia and impaired carbohydrate tolerance following the ingestion of dextrose.<sup>35,36</sup> Such patients, however, are probably

\* Amino acids, Stearns; aminogen, Mead Johnson.

not true diabetics, since carbohydrate metabolism returns to normal or near normal after recovery from the debilitating illness with closure and healing of the wound. The advantageous use of small doses of insulin in such cases as a means of stimulating wound repair has already been noted.<sup>35</sup> In this writer's opinion, this type of delayed wound healing occurs particularly in the elderly patient in whom the endogenous production of insulin, already diminished by pancreatic arteriosclerosis, is further curtailed by chronic illness, infection, suppuration, etc. Five to 10 units of unmodified insulin given before each meal frequently results in decided clinical improvement both generally and locally.

### Calcium Metabolism

Both normal ossification and the healing of fractures involves the deposition of calcium and phosphorus in an organic matrix situated at the epiphyseal-diaphyseal junction and at the site of the fracture, respectively. The mechanism at work in both instances is probably the same, the latter reflecting the same processes under stress. The various factors involved in ossification have recently been summarized:<sup>37</sup>

1. Adequate concentration of calcium in serum and tissue fluid
2. Adequate concentration of phosphorus in serum and tissue fluid
3. Adequate concentration of phosphatase in the provisional zone of calcification (this enzyme is necessary in order to liberate inorganic phosphorus from organic phosphoric esters at the site of calcification, thus permitting the combination of the released phosphorus with calcium to form calcium phosphate)
4. Adequate intake of calcium and calciferol (vitamin D) (this vitamin favors the absorption of calcium from the intestinal tract)
5. Adequate production of parathyroid hormone (this hormone maintains the calcium content of serum and tissue fluid at normal concentrations by favoring the urinary elimination of phosphorus)
6. Satisfactory pH in the matrix (increased local acidity inhibits calcification)
7. Normal concentration of magnesium in tissue fluid (increased amounts of this mineral also inhibit ossification)
8. Adequate concentration of vitamin C in blood and tissue fluid (the rate and degree of calcium deposition in bone is impaired in vitamin C deficiency<sup>38</sup>).

In the normal adult, the rate at which a fracture heals apparently cannot be augmented by the increased intake of calcium, vitamin D, and vitamin C. Of particular importance is the question whether these factors might influence

delayed union or nonunion of closed fractures. Assuming that local causes can be ruled out, such as deficient reduction, interposition of soft parts, deficient fixation, bone pathology (osteomyelitis, carcinoma, gumma, etc.), and prolonged immobilization with resultant atrophy and osteoporosis, what may be accomplished by general therapeutic measures?

In most cases of delayed union and nonunion, the various factors governing ossification enumerated above appear to play a negligible role, because fundamentally, the extra burden of a fracture is not an excessive strain on the normal mechanism.<sup>39, 40</sup> However, each case deserves a critical survey for possible disclosure of some metabolic abnormality. The following chemical examinations of the blood are in order: (1) serum calcium (to determine the necessity for calcium and vitamin D therapy); (2) serum phosphorus (to determine the necessity for increased phosphorus intake; excessive amounts of inorganic phosphorus cause acidosis, thus inhibiting calcification); (3) vitamin C concentration (the relation of this vitamin to ossification has already been discussed); (4) serum alkaline phosphatase (to rule out bone pathology, viz., Paget's disease, hyperparathyroidism, rickets, metastatic carcinoma to bone, etc.); (5) serum proteins (hypoproteinemia interferes with reparative processes;<sup>41</sup> moreover, a normal serum globulin would tend to rule out multiple myeloma).

In this writer's experience, cases of delayed union or nonunion of closed fractures presenting no obvious metabolic abnormality fail to respond to medical therapy. On occasions, however, calcium or vitamin deficiency will be disclosed and adequate therapeutic measures will be followed by, encouraging clinical results. The administration of androgenic and estrogenic hormones has been advised to stimulate the production of osteoblasts in senile or postmenopausal osteoporosis when found concomitantly with impaired healing of fractures;<sup>42</sup> the present writer has had no experience with sex hormones in this particular field.

Calcium is best administered as milk or as other dairy products. This may be supplemented by liberal doses of calcium gluconate or lactate (heaping teaspoonful) added to the milk and given one to two hours before meals three or four times daily (calcium is more readily absorbed from the fasting gut, since it precludes precipitation of the calcium by oxalates or fatty acids). Vitamin D concentrates (percomorph oil, drisdol, etc.) should be administered simultaneously in 5- or 10-drop doses several times daily to enhance the absorption of the calcium. In the older age group, because of the frequency of achlorhydria, dilute hydrochloric acid in teaspoonful-

# WAR WOUNDS OF COLON AND RECTUM

JOSEPH E. HAMILTON, CAPT., (MC), AUS

ABDOMINAL injuries constitute 2 to 3 per cent of casualties to leave the battlefield and of these Churchill<sup>1</sup> found the colon involved along with other viscera in 59 per cent and the colon alone involved in 36 per cent.

Shrapnel and bullets cause the great majority of intra-abdominal injuries; bayonets and non-penetrating violence cause comparatively few. Blast from bomb explosion, both in air and water, is an occasional cause of nonpenetrating trauma from the concussion of air or water upon the thoracic and abdominal wall. Air blast involves chiefly the lungs, causing patchy subserous and parenchymal hemorrhages. It only rarely produces serious intra-abdominal damage. Bomb and torpedo explosions in water produce varying intra-abdominal injuries in those submerged within a 20-yard radius.<sup>2</sup> In mild cases there are contusions of and hemorrhage into the walls of the colon and small gut, resulting in pain, distention, and occasionally melena. In more severe cases the hollow viscera are ruptured. The victim will usually be in some degree of shock, will complain of severe abdominal pain, and in over half the cases will have the desire to defecate. Nausea and vomiting and a board-like, markedly tender abdomen are the rule.

## Diagnosis

In nonpenetrating injuries, including those caused by blast, the decision must be made whether or not visceral injury requiring surgery is present. In the doubtful case, the procedure of greatest value is to observe closely for a while the patient, who, though not given sedatives, is otherwise made as comfortable and quiet as possible. Increasing pain, persisting local rigidity tending to spread, a gradually rising pulse rate, repeated vomiting, all point to subserosal injury. At all events, if the surgeon is not satisfied within two to four hours that interference is not necessary, he is obliged to operate. As Richard Charles<sup>3</sup> said, "Better to look and see than wait and see."

The decision to be made in the case of knife or projectile wounds is whether or not the peritoneal cavity has been penetrated, since penetration demands exploration. The presence of the entry wound in the abdominal wall is usually sufficient clue, but it must be remembered that bullets or shrapnel entering the chest, back, thighs, or but-

tocks may enter the peritoneal cavity. Of Gordon-Taylor's<sup>4</sup> cases only 60 per cent of entry wounds were in the anterior abdominal wall, while 20 per cent were in the back and 20 per cent in the buttocks. Shock from intraperitoneal bleeding or definite evidence of peritoneal irritation makes the diagnosis, but signs and symptoms of perforation may be surprisingly misleading.<sup>5</sup> Blood in the urine or blood obtained by stomach tube or rectal examination is of positive value. Nerve injury of the lower extremities will help localize the projectile's path. In the rush of the forward areas, x-ray examination for determination of pneumoperitoneum or for the location of a foreign body is seldom feasible. As a general rule, then, laparotomy must be performed at once if there is any likelihood of peritoneal perforation.

## Prognosis

The mortality from large bowel injuries so far in this war is probably in the vicinity of 50 per cent. In Table 1 are listed the statistics collected by the surgical consultants for three theaters of operations.

In injuries of the colon alone, hemorrhage is a less serious danger than is peritonitis. However, in the majority of cases other injuries coexist, such as laceration of liver or spleen, small bowel, mesenteric vessels, etc., in which severe bleeding is the rule. The dominating influence of hemorrhage on the outcome of penetrating abdominal injuries is shown by our Louisville General Hospital series.<sup>5</sup> The mortality of penetrating abdominal injuries with less than 500 cc. hemorrhage was 17.2 per cent. The mortality was 41.5 per cent with blood loss of 500 to 1,000 cc., and 64.6 per cent when it exceeded 1,000 cc. In this same connection Loria<sup>7</sup> quotes a mortality of 11.9 per cent in cases with slight hemorrhage, 39.2 per cent with moderate hemorrhage, and 93.2 per cent with large hemorrhage.

## Treatment

*Prophylaxis.*—Perhaps this may sound futile, considering the inevitable hazards of battle, but certain simple, self-protective measures are taught to combatants for use during bombings and strafings. The soldier jumps out of any vehicle he may be in and flings himself flat, face downward. If there is no ditch or slit-trench handy, he should press himself against a solid object such as the base of a wall, rock, etc. Sailors are taught to paddle away from the site of imminent explosion, in their life belts, belly up and feet first. Thus the back and not the abdo-

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 11, 1944.

From Walter Reed General Hospital, Washington, D.C.

men receives the impact of the concussion. This also prevents the funneling of water into the anus and rupture of rectosigmoid that occasionally occur when, in swimming away head first, the perineum is presented to the blast.

**Preoperative Care.**—If a soldier with an early perforating belly wound is found in shock he is almost certainly bleeding briskly internally. To delay surgery, hoping to bring him out of shock by the usual rest, warmth, and intravenous infusion of blood and plasma may be fatal. Intra-abdominal bleeding is active and does not tend to cease spontaneously. It is obviously futile, then, to expect even rapid intravenous replacement to compensate for vigorous bleeding from torn vessels. The earliest possible operation and ligation of bleeders is essential. It is of utmost importance, however, that plasma, or preferably blood, should not be delayed but should be running into a vein as rapidly as possible while the operation is going on.

Shock, when present in patients who have survived several hours before reaching the base, may be due to other causes besides hemorrhage, and in these some preoperative intravenous protein therapy may be indicated if it is not continued too long.

Preoperative passage of a stomach tube, to be connected with suction, is valuable, especially in upper gastrointestinal injuries.

**Anesthesia.**—The type of anesthesia used is less important than the expertness of the anesthetist. Spinal anesthesia is ideal when shock is not present. Ether, by closed system, with adequate oxygen is an alternative. In the forward areas pentothal has been used extensively and with satisfactory results. Churchill<sup>1</sup> emphasizes that intense pneumonitis from aspiration of gastric contents occurs more frequently than is realized and that the anesthetist should be prepared to perform bronchoscopy on the patient if aspiration is suspected.

**Incision and Closure and Debridement of Entry Wounds.**—For most purposes, a generous midline or paramedian incision is the most practical. A transthoracic approach<sup>14</sup> may be advisable when the missile crosses the upper diaphragm and abdomen, especially on the left side, and when major thoracic as well as upper abdominal injury

FIG. 1. Sites of election for colon exteriorizations in war injuries (borrowed from Col. F. S. Gillespie, RAMC).

is suspected. Closure by means of through-and-through heavy, nonabsorbable sutures can be rapidly done and will give the strongest wound and the one least likely to become infected.

An interesting fact pointed out by Gordon-Taylor<sup>5</sup> and Stabler<sup>6</sup> in reference to débridement of entry wounds is that such wounds, when located in the back or buttocks, should be excised before laparotomy, because rolling a severely wounded patient into a prone position after he has undergone extensive surgery lying on his back may throw him into severe shock.

**Exploration.**—The first concern in cases coming to the table in shock is the control of hemorrhage. With a foreknowledge of the approximate path of the slug, the surgeon can examine the most likely sites of hemorrhage first. Suction is of the greatest value in clearing the field of blood and clots. Blind clamping for bleeders is futile and dangerous. Proximal digital compression of large vessels until their bleeding points can be identified and controlled saves valuable time and blood; thus, bleeding from a laceration in the liver can be controlled by compressing the hepatic artery and portal vein through the foramen of Winslow. Likewise, mesenteric hemorrhage can be controlled by pinching the superior mesenteric or one of its branches. In this connection Ogilvie<sup>7</sup> made the dictum "no mass ligation, no stitches, no catgut." Mass ligation may

FIG. 2. Case 1. Shrapnel entry wounds, right buttock.

imperial too much blood supply; stitches or suture ligature will usually start up fresh bleeding. Silk or cotton ligature is preferable to catgut, which may slip off. In short, expose the bleeder, clamp and ligate with silk or cotton tie.

With the hemorrhage stanching an orderly search must be made for injury in all viscera, solid as well as hollow, that could possibly have been damaged. The transverse colon is inspected to both flexures and from there to the cecum on one side and to the rectum on the other. A very practical maneuver used by Major Foster, RAMC, was passed on to me by one of the American surgeons working with him. When there is a question whether or not a bullet which entered the buttock or perineum might have penetrated the true pelvis or pouch of Douglas, simply swab the pelvis with a sponge stick. Absence of blood on the sponge rules out perforation. Time is saved in the small bowel survey by placing a Babcock forceps on the first loop picked up and then, with this as a marker, reading both ways to the ligament of Treitz and to the ileocecal valve.

**Repair.**—The guiding principle of military surgery of the colon is to exteriorize the damaged segment if at all possible. The colon beyond the proximal ascending portion should, when perforated, be exteriorized through a small separate muscle-splitting incision placed in the lateral abdominal wall, as illustrated in Fig. 1. A single small laceration may be placed at the apex of a knuckle colostomy. In case of more extensive damage, whether from impaired blood supply or large or multiple lacerations, a double-barrel type colostomy should be constructed, and if time permits, the two limbs should be sutured together for 3 or 4 inches to create a spur that can be later crushed to restore continuity. Even

FIG. 3. Case 1. Showing original exploratory incision and exteriorization of sigmoid.

lesions of ascending and descending colon can be exteriorized in many cases if the avascular external leaf of mesentery is divided and the bowel and its mesentery, including hepatic or splenic flexure, be freely mobilized medially. If exteriorization is impossible, the lacerations should be sutured (transversely to the long axis of the bowel) and a proximal colostomy for exclusion performed. When a perforated colon must be sutured it is important to remember that, except in occasional tangential injuries, one hole means another one on the other side of the gut to be found and sutured.

Wounds of the terminal ileum, cecum, and ascending colon, other than a simple cecal perforation that can be converted into a tube colostomy, present an unsettled problem because of the hazard of irritating ileostomy drainage. Churchill<sup>1</sup> advocates in early favorable cases transplanting ileum into colon distal to the injury and exteriorizing the damaged segment. In less favorable cases he presents the alternatives of a Mikulicz type of resection of terminal ileum and colon, or bringing out the ileal and colonic limbs through separate incisions in the right lower quadrant

FIG 4 Case 2 Barium study revealing short fecal fistula of descending colon

FIG 5 Case 2 Showing (1) entry and incision and drainage wound, left iliac region, (2) left McBurney incision for closure of fecal fistula, (3) original exploratory incision, (4) transverse colostomy closure wound

and subcostal region, respectively. Blackburn<sup>10</sup> prefers in most cases simply to suture the lacerations and leave the bowel within the belly.

Where there is perforation of rectum or anus above the sphincter a proximal double barrel inguinal sigmoidostomy for exclusive is performed. The perforations themselves may be inaccessible for suture. The possibility of injury to rectum or of intraperitoneal penetration should be kept in mind in all entry wounds around the buttocks, upper thighs, and perineum.

Whenever retroperitoneal tissues are soiled with lower bowel contents, drainage should be established through the flank. Perforation of rectum or anus requires free drainage posteriorly. In some cases this may be facilitated by excision of the coccyx.

**Chemotherapy**—The forward surgeons seem unanimous in advocating prophylactic sulfonamides, though there is not, as yet, a consensus as to the relative merits of local and general administration. The U.S. Army stresses the oral and parenteral routes. Sulfadiazine is now becoming

popular. It is interesting to note that as the time lag between injury and operation increased (and with it the incidence of peritonitis might be expected to increase), the effectiveness of the sulfadiazine became increasingly apparent.

We employ a preoperative course of sulfasuxidine before all elective bowel surgery. This, together with a proper maintenance of red cells, proteins, and vitamins, has proved to be the greatest protection against infection we have yet encountered.

**Antishock Measures**—In the early hours after operation, the tendency to shock should be vigorously combated by blood and plasma infusion. Increasing emphasis is being placed, especially by the British, upon the superiority of whole blood over plasma in combating shock, particularly that due to hemorrhage. Oxygen either by nasal catheter or tent, if available, is valuable in correcting tissue anoxemia.

**Decompression** by Wagensteen suction applied to a simple stomach tube is mandatory in all bowel cases until the threat of ileus is past. Likewise of great importance is thorough dilatation of the anal sphincter at the conclusion of the operation, and the periodic passing of the rectal tube thereafter till the patient begins to expel gas spontaneously.

**Evacuation to the Rear**—This entirely military problem is one of the most important to the sur-

TABLE 2.—EFFECT UPON MORTALITY OF INTRAPERITONEAL SULFADIAZINE THERAPY

Hours between Injury and Operation	Mortality	
	With Sulfa (Percentage)	Without Sulfa (Percentage)
1-12	48.1	48.4
12-24	40.0	51.2
24-48	35.7	44.0
Over 48	50	75

vival of the abdominal case. Only severe burns approach abdominal injuries in their inability to stand transportation. One of the most essential requirements to the safe outcome of these patients is the assurance of a seven- and preferably a ten-day stopover after operation. Yet the briefest possible delay should be allowed in getting the soldier with abdominal wounds to surgery. For this reason, most of these patients are operated upon at the surgical unit that happens to be attached to the casualty clearing station three to ten miles behind the front lines.

**Maintenance of Nutrition.**—The importance of postoperative maintenance of hemoglobin, red cells, proteins, and vitamins is becoming generally appreciated. That a patient may have the best chance of sound healing and avoidance of complications his red cells *must be made* to number at least four million, his hemoglobin at least 80 per cent, his plasma proteins at least 6.0 Gm., and his vitamin intake must be assured by one or two multivitamin tablets thrice daily. The fact that some patients will get well after operation even though they have anemia and hypoproteinemia and vitamin deficiency is no argument to the contrary. The above requirement is met by supplementing a high-calory, high-carbohydrate, and high-protein diet with vitamins, ferrous iron, whole blood, and the new amino acid preparations for oral and intravenous use. These last are cheaper and probably more effective in restoring tissue and plasma proteins than is plasma.<sup>11</sup>

### Management of Late-Stage Injuries

When the soldier, surviving colon injury, reaches us at the general hospital in the zone of the interior, he presents a colostomy and, unfortunately, he often also presents other disabilities such as abdominal sinuses, nerve injuries, extremity amputations, etc. The best way to describe this final phase of treatment will be to present illustrative cases.

### Case Reports

**Case 1.**—The patient was wounded in the right buttock and lower leg, on February 16, 1943, on Anzio beachhead, by mortar shell fragments. Fig. 2 shows the entry wounds in the right buttock. There were no exit wounds. At an evacuation hospital ten hours later exploration through a low mid-

line incision revealed perforation of sigmoid and small gut. The perforations of the small bowel were sutured and the sigmoid was exteriorized through the left groin. Later that day amputation of the right leg was performed. The soldier made a smooth convalescence and arrived at Walter Reed General Hospital in good general condition with a well-functioning sigmoidostomy (Fig. 3).

**Comment.**—This case illustrates the potential abdominal injury associated with entry wounds of the buttocks. Although no record is available, we may assume that the gluteal entry wounds were débrided before the abdominal exploration. It yet remains to apply a spur-crushing clamp and then to close the stoma. The patient will be placed upon sulfasuxidine both by mouth and as an irrigant of the distal rectosigmoid for five days before operation.

**Case 2.**—In Tunisia, on April 29, 1943, the patient received a shrapnel fragment in the left side which fractured the left iliac crest, lacerated the sigmoid colon, and was retained in the abdomen. He took sulfa tablets at the time of injury and received plasma therapy for shock twelve hours later at a field hospital, which he reached after a four-hour litter carry though the hills followed by a four-hour ambulance ride. The following morning, the soldier was transferred by ambulance to an evacuation hospital where, under inhalation anesthesia twenty-six hours after injury, abdominal exploration was carried out. The lacerations of the descending colon were sutured but not exteriorized. On May 20, 1943, three weeks later, two fecal fistulas formed in the region of the entry wound. In late June an abscess developed in the left flank and on July 9, 1943, a transverse colostomy for exclusion was carried out and the abscess was drained by an incision connecting the two fecal fistulas, and several pieces of necrotic ileum were removed. The soldier arrived at Walter Reed General Hospital September 18, 1943, and at this time he presented, in addition to the transverse colostomy, a single small fecal fistula just above the left iliac crest. A barium enema, with a probe inserted into the tract (Fig. 4), revealed what appeared to be a very short fistula connecting with the colon through the defect in the iliac crest. On October 14, 1943, after five days' preparation with sulfasuxidine, through a left McBurney incision, the descending colon was freed from the fistula and closed transversely. The transverse colostomy was closed November 9, 1943. Persistence of discharge (nonfecal) through the fistula necessitated a final débridement on February 11, 1944, of the region around the left iliac crest and the removal of a small piece of shrapnel originally thought to be of no significance. Final healing occurred April 10, 1944 (Fig. 5).

**Comment.**—It probably would have been better judgment in this case, especially in view of the prolonged time-lag between injury and operation, to have simply exteriorized the laceration of the descending colon. If this were impossible, a

FIG. 6. Case 3. Lipiodol study of branching abdominal sinus tract.

FIG. 7. Case 3. From patient's right to left. (1) Exit wound over right greater trochanter. (2) Incision for ureterovesical anastomosis. (3) Suprapubic sinus opening. (4) Original lower midline exploration incision. (5) Transverse colostomy closure wound.

proximal colostomy of discontinuity should have been done.

**Case 3.**—On April 23, 1943, near Mateur, the patient was wounded by a sniper's bullet which entered just above the left greater trochanter, traveled transversely across the pelvis, and made its exit just above the right greater trochanter. In transit it perforated the sigmoid and ileum, severed the right ureter just above its junction with the bladder, and injured the right lumbosacral plexus. Two or three hours later, at an evacuation hospital, the abdomen was explored through a low midline incision. The perforations of the ileum and sigmoid were sutured, a suprapubic cystostomy was performed, and the belly was closed without colostomy or exteriorization of the sigmoid. The soldier had a stormy postoperative course. A transverse colostomy was done June 4, 1943, because of a fistula between the bladder and the colon. He reached Walter Reed General Hospital September 16, 1943, 42 pounds underweight, with a functioning transverse colostomy, a urinary fistula at the site of the old cystostomy, and right lower leg paralysis, chiefly paroneal. On the urologic section on October 12, 1943, the right ureter was successfully implanted into the bladder. The patient was then transferred to the general surgery section and a lipiodol study on November 24, 1943 (Fig. 6) revealed a sinus extending into the pelvis from just above the right trochanter. Here it forked, one branch extending anteriorly to the old cystostomy wound, the other backward to a puddle between rectum and sacrococcyx. There was also a superficial tract extending up and backward around

the right ileum. Cystourograms and methylene blue studies ruled out any connection with the ureter or bladder. On December 3, 1943, the coccyx was excised and the retrorectal pocket was explored. A quantity of necrotic tissue but no foreign bodies were evacuated. The transverse colostomy was closed January 3, 1944. Some calcareous material was discovered in the persisting tracts and this was largely dissolved by irrigations with Subey's solution. On April 11, 1944, the three limbs of the sinus (right trochanteric, suprapubic, and coccygeal) were curetted under anesthesia as far as could be reached. At the present time, although considerable shrinkage has occurred, the suprapubic and coccygeal branches still persist and communicate.

**Comment.**—Here again the sigmoid perforation should probably have been exteriorized at the original operation. Failure to discover and repair the severed right ureter under the circumstances is understandable. The general management must have been good to have salvaged at all this soldier with his many injuries. The sinuses still present a problem. Should they persist much longer, a radical extra- or transperitoneal exploration through the right abdomen is contemplated. From the much-scarred abdomen shown in Fig. 7, it is obvious that this will be a formidable procedure. Needless to say, any

neurosurgery on the right lumbosacral plexus has been thus far out of the question. However, the soldier walks fairly well with his spring toe-drop brace.

### Summary

1. The cause, diagnosis, prognosis, and surgical management of war wounds of the colon and rectum are presented.

2. The following special factors peculiar to war surgery are stressed:

(a) The necessity of exteriorizing injuries of the colon.

(b) The problem of evacuation of the abdominal case.

3. Cases are presented to illustrate the late management of injuries of the colon and rectum in the zone of the interior.

### Discussion

Dr. A. W. Martin Marino, *Brooklyn*—It is easy to see from what we have just heard that our fighting men are receiving as fine surgical care as is possible under battle conditions. Although the incidence of abdominal injuries is only 2 or 3 per cent, we can

understand the importance of prompt and proper attention to such injuries. The measures employed immediately after the injury will govern what and how much can be done for the wounded soldier later on. The very orderly and rational routine presented by Captain Hamilton certainly leaves no room for criticism.

It seems to me that the points to emphasize are: first, to operate if there is any doubt of intestinal involvement; second, to use the utmost gentleness in exploring the peritoneal cavity. The performance of an exploratory laparotomy with negative findings is infinitely less risky than the postponement of operation in a patient with a perforated intestine. An anesthetic which permits the patient to be perfectly relaxed helps considerably in the employment of gentleness.

Exteriorizing operations are most logical when time is an important factor, and when the poor condition of the patient prohibits more extensive surgery. It must be kept in mind that when first seen these patients have not received any preoperative preparation, so that only absolutely essential surgery is permissible.

In examining the small and large intestine for perforations and tears, a definite, systematic search, as described by the speaker, saves time and helps prevent shock. The placing of a black silk suture superficially in the mesentery or the wall of the first loop of intestine which presents itself, as described by R. W. McNealy,\* serves to identify a loop of bowel that has been examined and therefore need not be handled again.

It is interesting to me that blood is preferred to plasma in these cases because I, too, prefer blood in my work.

I am certain that after this war is over our management of rectal and colonic injuries will be considerably revised because of the experience and observations of medical officers like Captain Hamilton.

\* *S. Clin. North America* 24: 79 (1944).

### VOCATIONAL TRAINING REHABILITATES DISABLED

More than 75,000 men and women who were unable to hold a job because of some crippling disability have gone on the 1944 payrolls as a result of assistance given them under the Federal-State program for vocational training, Federal Security Administrator Paul V. McNutt announced on October 29. This total, much larger than that for any previous year, comes, he said, from a tabulation of reports made by the State boards of vocational education to the Office of Vocational Rehabilitation of the Federal Security Agency.

Emphasizing the economic importance of the rehabilitation program, Mr. McNutt cited the results obtained by the District of Columbia Rehabilitation Service during the fiscal year 1943-1944. A summary of its report accounts for the rehabilitation of 435 handicapped persons. Of this number

161 were placed in government jobs and 274 in jobs in industries essential to the civilian economy.

The annual earnings of the 435 persons rehabilitated, it was pointed out, will amount to \$714,636 the first year after their rehabilitation. The average weekly wage was raised from \$28.65 in the fiscal year 1942-1943 to \$31.59 in 1944.

Of all the rehabilitated cases, 76, or 17.5 per cent, were referred by the District of Columbia Board of Public Welfare. The annual earnings of this group alone will amount to at least \$103,320. If these persons had not been restored to remunerative employment, Mr. McNutt said, it would have cost the Board of Public Welfare \$25,016 as an annual recurring expense, while the cost of rehabilitation amounted to only \$3,592.—*Release from the Office of War Information, Oct. 29, 1944*

# Diagnosis

## CLINICOPATHOLOGIC CONFERENCES

### FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

Date October 26, 1944

Conducted by Dr. Harry A. Solomon

DR. MARILYN T. SCHIFFMAN: J. V., a 17-year-old white girl, was admitted to Bellevue Hospital on July 14, 1943, with chief complaints of pain in the left side of the chest of one day's duration, and increasing dyspnea and orthopnea, joint pains, and intermittent feverishness of three months' duration.

The patient had known since childhood that she had heart trouble, and was told that she had been born with it. She was followed in the Cardiac Out-Patient Department for congenital cardiac disease, and by her local medical doctor, and was quite well on only moderate limitation of activity. On about April 4, 1943, she had a sudden onset of pain in the left chest and axilla, feverishness, and pain in both ankles, which gradually extended to the knees. This was not associated with swelling or redness. The chest pain was sharp, nonradiating, and aggravated by coughing and respiration, but was not associated with bloody sputum. These symptoms subsided spontaneously, only to recur with increasing frequency up to the time of the present illness. At the same time dyspnea (which rapidly progressed to the rest type), orthopnea, weakness, fatigue, and anorexia developed. There was no nausea, vomiting, constipation, or diarrhea. There was no previous history of joint pains, epistaxis, cyanosis, palpitation, or edema. There had been occasional colds and sore throats, but none in recent months, and there was no knowledge of previous rheumatic fever. The patient claimed a 20-pound weight loss in two months and weighed 76 pounds on admission.

She had been admitted to another hospital in February, 1942, and was treated for fifteen days for spleen and liver trouble, and then was discharged as improved. The past history and family history were otherwise noncontributory.

**Examination on Admission.**—Examination revealed a pale, emaciated, dyspneic, orthopneic white female who appeared chronically ill but was not in acute distress.

The temperature was 102.4 F, pulse, 120, respirations, 28, and blood pressure, 118/60—0

Head and ear, nose, and throat. Negative.

The cervical nodes were palpable. Moderate pulsations and systolic thrill were noted in the supraclavicular fossa. Moderate carotid pulsations were present. The trachea was in the midline. There was a marked hyphoscoliosis.

The left lung showed absent fremitus in the lower half (anterior and posterior) with increased resonance in the upper one-half, where bronchovesicular breath sounds with a peculiar amphoric quality were heard. There were a few moist rales below the angle of the scapula. The bronchovesicular breath sounds and a few moist rales were heard in the upper two-thirds of the right chest (anterior and posterior).

The point of maximum intensity was in the fifth intercostal space just outside the inferior axillary line, with visible pulsations. The first sound was almost inaudible at the apex. There was a suggestive systolic thrill at the apex and a loud systolic thrill at the base. The aortic second sound and the pulmonary second sound were equal. A harsh, loud, low-pitched systolic murmur was heard best at the third left intercostal space, but was transmitted over the entire chest. The rate was rapid and regular with an occasional dropped beat.

The liver was felt two fingerbreadths below the costal margin. The spleen was at the level of the umbilicus. There was moderate left costovertebral angle tenderness.

The extremities showed moderate cyanosis and clubbing of fingers.

**Laboratory Data on Admission.**—The red blood count was 4.3 million, hemoglobin 12.5 Gm. The white blood count was 17,750 with 82 per cent polymorphonuclears and toxic granules. The urinalysis was negative, except for a few hyaline and granular casts. The erythrocyte sedimentation rate was 9 mm. per hour.

**Course.**—The patient ran an irregularly febrile course with rises to 101 F and occasionally as high as 102 F. An x-ray on July 26 revealed a massive effusion of the right lung field, marked enlargement of the heart in the transverse diameter, and displacement to the left. On July 30, resolution of the effusion revealed a pneumonic process of the right lower lobe with thickening of the interlobar and axillary pleura.

The right lower lobe consolidation persisted to the end of the course and on November 9 involvement of the lower one-third of the left lung was noted.

There was a progressive slow decrease in the white blood count and differential counts with occasional moderate elevations to the termination of the course. The erythrocyte sedimentation rate rose to 65 on July 28, but fell to 12 on August 4, and never rose above that. The electrocardiograms were entirely normal.

Subsequent urine analyses showed red blood cells, white blood cells, casts, and increasing albumin to 4 plus.

Concentrating power remained good until December, when it became fixed below 1.008. Blood cultures were done weekly and remained negative, except for those of August 13 and 23 and September 3, which were positive for streptococcus of an undetermined type. Terminally, the urea nitrogen rose to 45 mg. per cent and creatinine to 1.8 mg. per cent. The blood pressure remained normal.

The patient's condition remained essentially the same for a while. On August 23, a course of sulfadiazine therapy was begun and 7 Gm. were given by mouth in two days. On August 25 triple typhoid-vaccine fever therapy was begun, and 3 Gm. of sodium sulfadiazine was given intravenously at the height of the fever. This was repeated on August 27 and then every two to seven days for ten treatments with some improvement—that is, reduction in the size of the spleen and increase in general well-being. On September 24, she developed left upper quadrant pain and a splenic infarct was suspected. Repeated pulmonary infarctions occurred.

It was decided that the murmur heard in systole was caused by a patent ductus arteriosus and the patient was transferred to the Chest Service for ligation of the duct on November 22, but her condition became worse so rapidly that ligation was postponed. On December 1, following digitalization for congestive failure, showers of petechiae were noted. The patient's course was rapidly downhill; petechial manifestations continued, and on December 12 the patient died.

## Discussion

DR. HARRY A. SOLOMON: This interesting girl was on the medical ward for a long time and provoked a good deal of controversial discussion, particularly with regard to her cardiac lesions.

She was sheltered from infancy onward as a cardiac invalid, and classified as having a congenital anomaly at the Cardiac Clinic, which she attended for most of her young life. Of course her stunted body growth, impaired nutritional state, and a congenital anomaly of the spine

lent further support to the diagnosis of congenital heart disease.

No indication of rheumatic fever was obtainable. In fact, she carried on quite well and the only history of previous illness was that fifteen months prior to admission to Bellevue, she was treated at another hospital for an attack of severe abdominal pain and discharged after fifteen days with a diagnosis of liver and spleen disease.

On admission her appearance of chronic wasting disease with marked respiratory distress because of air-hunger and chest pain dramatically confirmed the history of months of suffering with fever, cough and expectoration, orthopnea, anorexia, sweating, exhaustion, etc. Subacute bacterial endocarditis was suggested by the chronic septic state with cardiac murmurs, and pulmonary embolizations and infarctions by the episodic sharp chest pains associated with cough, dyspnea, and hemoptysis. After a while positive blood cultures with a streptococcus organism confirmed the first condition while characteristic x-ray findings in the chest substantiated the second. Regarding the cardiac signs, there was a prolonged systolic rough murmur and thrill over the third intercostal space to the left of the sternum. This murmur seemed to be transmitted over the entire base of the heart, but was not heard posteriorly. The pulmonic second sound which was audible at first subsequently disappeared. Also over the mitral area there was a short presystolic murmur and thrill of mild intensity. No aortic or tricuspid murmurs could be made out, although it is only fair to state that evaluation of physical signs in the chest was difficult not only because of the rapid heart rate, but also because of the deformity of the chest which displaced the heart, the extensive rales which filled the chest, and the patient's inability to cooperate because of extreme pain and dyspnea.

Bacterial endocarditis of the valves of the pulmonary artery due to a streptococcus organism could adequately explain the clinical picture with the signs of pulmonary stenosis, pulmonary infarction, septic state, and paucity of positive blood cultures. A pre-existing defect of this valve of congenital origin could be assumed from the history.

When it became apparent that sulfonamide and supportive therapy was not controlling the infection, treatment with combined induced hyperpyrexia and sulfonamides was tried, but with only transient benefit.

Naturally, with bacterial endocarditis and a congenital heart lesion, it was devoutly hoped that patent ductus arteriosus could be proved and the patient could have the opportunity of surgical ligation as a life-saving measure. But, unfortunately, adequate criteria for this anomaly

were lacking. Granting that a diastolic murmur is not always present in this condition, the systolic murmur was not heard over the posterior chest and the x-ray showed no significant enlargement of the pulmonary artery or its main branches. One might comment on the enormous size of the spleen, which extended well below the umbilicus and seemed larger than could be accounted for on the basis of chronic sepsis and cardiac cirrhosis. The possibility of thrombosis of the splenic vein was thought of because of the history of an episode of severe abdominal pain with "liver and spleen" disease diagnosed during a previous hospitalization. There were, however, no signs of splenic dysfunction.

Of interest also were the changes of progressive renal damage and renal insufficiency which developed as the bacterial endocarditis infection continued with the focus limited to the right heart and the lungs serving as organs of immunity and barriers to the systemic spread of the infection.

The progressive and extensive involvement of the kidneys with focal embolic glomerular nephritis explains the urine findings with persistent red cells, impaired concentrating ability, and rapid accumulation of very high sulfonamide blood levels, as well as renal failure. Without gross hematuria or hemoglobinuria one would not expect renal infarction.

With the patient's condition getting steadily worse, she was transferred to the Chest Service for further study for possible patent ductus arteriosus with more hope than expectation of finding this condition or altering the prognosis.

So, finally, on the basis of our interpretation of the developing clinical picture presented by this patient, the following pathologic findings can be expected:

Subacute bacterial endocarditis due to a streptococcus organism.

The bacterial nidus developed in the valves of the pulmonary artery, which was defective on a congenital basis. The predominant embolic phenomena were in the lungs with extensive infarction, and in the kidneys with widespread focal glomerular nephritis.

The congenital anomaly of patent ductus arteriosus could not be established.

Rheumatic heart disease with mitral stenosis was suspected.

Thrombosis of the splenic vein was considered.

Dr. NAMMACK: The superimposing of subacute bacterial endocarditis on a congenital cardiac defect is common. In my experience, we always have trouble in identifying the lesions and without an electrocardiogram, we would have difficulty. The splenomegaly was probably the result of a previous splenic infarct and the spleen

remained large. The streptococcus may have been nonpathogenic and appeared and disappeared.

Dr. KELLY: There are several things that occur to me. First—how long were her fingers clubbed? All her life?

Dr. SOLOMON: They were only slightly clubbed and I think that this might be explained on the basis of the chest deformity.

Dr. KELLY: I doubt the presence of a patent ductus arteriosus. There was no machinery murmur, no electrocardiogram changes consistent with the diagnosis—the murmur that was heard was not transmitted to the back. I think that there must have been a malformation of the pulmonary valve with endocarditis engrafted on it.

Dr. TRUBCK: One thing we could be sure about was pulmonary embolization. She had hemoptysis and consolidation. About the question of a patent ductus arteriosus—there was a systolic thrill and murmur. The second pulmonic sound was good. The x-ray did not show prominence of the pulmonary artery and the electrocardiogram did not show right axis deviation.

The murmur was not characteristic of patent ductus arteriosus. Because of the negative confirmatory findings, I felt that this was pulmonary stenosis and not patent ductus arteriosus. Chronic sepsis probably produced the splenomegaly and has nothing to do with infarction in this right-sided endocarditis.

Dr. SOLOMON: Is it required to have the typical murmur to diagnose patent ductus arteriosus?

Dr. NICHOLSON: I remember two cases in point. In one the murmur, which had been typical, disappeared years before death, but the patent ductus arteriosus was found at necropsy. In the other, recordings of the murmurs established the diagnosis.

Dr. JOHANNSEN: Dr. Solomon, how do you tie up the loss of renal function with subacute bacterial endocarditis, especially since there was no evidence for acute diffuse glomerulonephritis?

Dr. SOLOMON: You admit the evidence for renal damage. It is reasonable to assume that this patient had very extensive focal embolic glomerulonephritis. In the presence of subacute bacterial endocarditis, there can be sufficient damage to the glomeruli to dangerously impair renal function.

Dr. WASHBURN: Why is that important in this case?

Dr. SOLOMON: Because we gave sulfadiazine and with doses of 1-2 Gm. got blood levels as high as 16 mg. per cent.

Dr. JOHANNSEN: Did you fluoroscope the patient to observe a hilar dance?

Dr. SOLOMON: No, she was always too sick

for that. Dr. Koffler, can you make the diagnosis of patent ductus arteriosus with only a systolic murmur?

DR. KOFFLER: Yes, it is not necessary to have a diastolic murmur.

DR. NICHOLSON: What did the electrocardiogram show?

DR. SOLOMON: It was normal. There was no right axis deviation.

## Presentation of Pathology

### Anatomic Diagnosis

Rheumatic heart disease with involvement of pulmonary, tricuspid, and mitral valves

Subacute bacterial endocarditis of the pulmonary valve, with partial occlusion of pulmonary orifice

Hypertrophy of heart, right ventricle and auricle

Chronic focal myocarditis

Pulmonary emboli, multiple

Infarcts of lungs, with liquefaction necrosis of two infarcts

Splenic tumor

Focal embolic glomerulonephritis

Acute ulcers of duodenum

Scoliosis of dorsal vertebra with asymmetry of chest

DR. HENRY SPITZ: This case presented several interesting features at autopsy. Although there was widespread rheumatic heart disease, the

aortic valves were spared but the pulmonic cusps were widely involved. The polypoid vegetations engrafted upon the pulmonary cusps apparently caused considerable stenosis of the pulmonary ostium. The valves were widely destroyed by the inflammatory process and the vegetations contained large colonies of bacteria and were partly covered by endothelium. The ductus arteriosus (Botallo's) was completely obliterated. Infarcts present in the lungs were old and recent and two of them were partly liquefied. Arteries and veins in the infarcted areas showed severe inflammatory changes of their walls with thrombosis. The spleen was more than four times its normal size and presented the histologic picture usually seen in chronic septic conditions. There were no infarcts and no obstruction of the splenic vein was found. The focal glomerulonephritis was rather widespread, but few of the glomeruli were completely destroyed. There was considerable hemorrhage into Bowman's capsules and the convoluted tubules. There were ulcers in the initial portion of the duodenum which were quite recent, showed no scarring, and developed possibly on an embolic basis. Other anatomic findings pointing to heart failure and chronic embarrassment of the pulmonary circulation were clubbed fingers and effusions in the left pleural and peritoneal cavities. The right pleural space was entirely obliterated by fibrous adhesions.

## SCIENTIFIC EXHIBITS

1945

### ANNUAL MEETING

Applications for space for the scientific exhibits should be made directly to

Dr. J. G. Fred Hiss,  
505 State Tower Building,  
Syracuse 2, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee.

Exhibits dealing with Industrial Health are especially desired.

The Annual Meeting will be held April 30-May 3, 1945, Hotel Statler, Buffalo.

*The list will be closed on January 20, 1945.*

PETER IRVING, M.D., *Secretary*

# Case Report

## URINARY SUPPRESSION FOLLOWING THE USE OF SULFADIAZINE

MURRAY F. BELL, MAJ., (MC), MILTON CANTOR, CAPT., (MC), AND PHILIP GREINLEY, CAPT., (MC), AUS

SULFADIAZINE has been regarded as one of the most innocuous drugs of the sulfonamide group, especially with regard to the urinary tract. This is due to the fact that only about 10 per cent of the drug is conjugated in the body, and that, although the acetylated sulfadiazine is therapeutically inactive, it is even more soluble in urine than the free form.

Raines,<sup>1</sup> in reporting a case of sulfadiazine toxicity, states that renal complications following the use of sulfadiazine have been reported in 3 to 4 per cent of a series of about 1,500 grouped cases treated, and in only one instance did urinary suppression occur.

The following case of hematuria, oliguria, and bilateral ureteral obstruction after sulfadiazine therapy was observed. It is reported to bring further attention to renal complications from the use of this drug, and to emphasize the rapidity with which the above-mentioned complications may occur.

### Report of Case

L K, a white soldier, aged 35, was admitted to the 210th General Hospital on November 2, 1942, complaining of cough, malaise, and weakness of five days' duration. The past history was irrelevant. The temperature on admission was 102.2 F., pulse rate 96, and respiratory rate 20 per minute. Subcrepitant rales were audible over the right mid-lung anteriorly, and roentgenograms of the chest revealed consolidation of the right middle lobe. The heart was normal, rhythm regular, and the blood pressure 120 systolic and 85 diastolic. On admission, the red cell count was 4,150,000, hemoglobin was 80 per cent, and the white blood count was 8,000, with 63 per cent polymorphonuclear.

The ur

for ova parasites were negative. Sputum typing revealed a few pneumococci which were not type-specific with the Neufeld Quellung reaction. A diagnosis of lobar pneumonia, right middle lobe, was made.

In view of the patient's good general condition, and the fact that the so-called primary atypical pneumonias seen in this region do not respond to the sulfonamide drugs, chemotherapy was withheld. However, when the fever persisted and the patient appeared more toxic, sulfadiazine was begun on November 5 with an initial dose of 3 Gm., followed by 2 Gm. four hours later, and 1 Gm. every four hours thereafter. The following day the tem-

November 6-7, he had eight to ten watery bowel movements. He then suddenly became restless and began to com-

plain of difficulty in urination. This manifested itself not in actual pain, but in a sense of an inability to void with satisfaction. He could only pass about 10 cc. of a reddish urine. In addition, he was seized with an "aching" in the lower quadrants of the abdomen. Soon thereafter, forty-six hours after institution of sulfadiazine therapy, he voided 30 cc. of a frankly bile he had received a total. This was immediately later another 5 cc. of passed. Microscopic red blood cells and 5 to free and acetylated, per high-power field. At this time the blood nonprotein nitrogen was 41 mg per cent and the creatinine 1.9 mg per cent. The blood pressure was 130 systolic and 100 diastolic.

Fluids were forced both orally and intravenously. At 11:30 A.M. he voided 300 cc. of a pinkish urine, much clearer than the previous specimens. In view of this apparently favorable course, it was decided to defer cystoscopy and continue a conservative regimen. The diarrhea was effectively controlled by the oral administration of bismuth and tincture of opium.

Microscopically, the urine contained 6 to 10 red cells, and 3 to 4 free and acetylated sulfadiazine crystals per high-power field. The blood pressure on November 8 was 125 systolic and 90 diastolic. During the second twenty-four-hour period, November 8-9, the total fluid intake was 3,620 cc., the urinary output 1,655 cc., and the vomited material 120 cc. The urine showed 3 plus albumin, 10-15 red blood cells, and many free and acetylated sulfa-

to 102.4 F. increased dullness, with numerous subcrepitant and coarse rales over the right mid-lung field and scattered rhonchi throughout both lungs. From 7:00 A.M. to 4:00 P.M. of November 9 he had voided only 200 cc. of urine. His blood pressure rose to 175 systolic and 105 diastolic. The blood nonprotein nitrogen was 46 mg. per cent. The temperature fluctuated between 99 F. and 100 F. He vomited small amounts and complained of sharp pains in the right flank and right lower quadrant of the abdomen. The urine had a pinkish coloration. A cystoscopic examination was therefore decided upon.

**First Cystoscopy**—Under novocaine instillation a Brown-Buerger 24F cystoscope was easily introduced into the bladder. The urine was cloudy and bloody, and contained many yellow particles. The mucosa appeared fairly normal. The right ureteral orifice was easily seen. It was surrounded by a slight amount of edema. The ureter was normally active. The left ureteral orifice was completely obscured by bullous edema, and numerous

\* From the Medical and Urological Services, 210 General Hospital, New Orleans

small hemorrhages. Very occasionally, small spurts of blood emanated from within this area.

A 6F catheter was inserted into the right ureter for 27 cm. A soft obstruction was met and easily overcome at 6 cm. Many small particles, similar to those seen in the bladder, escaped from the ureter around the catheter as it was introduced. The urine flow was rapid and in a continuous stream. The urine was hazy and contained numerous free and acetylated forms of sulfadiazine crystals. The kidney pelvis was lavaged with 2 per cent sodium bicarbonate. The left ureteral orifice could not be seen or catheterized.

The patient was returned to bed with the right ureteral catheter *in situ*, and orders were given to irrigate the catheter at definite frequent intervals, with a 2 per cent sodium bicarbonate solution.

The catheter drained freely. The fluid intake for the twenty-four-hour period November 10-11 was 6,136 cc. and the urinary output 1,647 cc. The urine again assumed a reddish color. The blood pressure on November 11 was 150 systolic and 100 diastolic. The temperature was 102 F., the blood nonprotein nitrogen was 48 mg. per cent, and the creatinine was 2.4 mg. per cent. A continuous slow intravenous infusion of 5 per cent glucose in normal saline, which had been started right after the cystoscopy, was continued for the following thirty-six hours. In addition, the patient received orally 1 Gm. of sodium bicarbonate every one to two hours, whenever the urine gave an acid reaction to litmus paper.

During the twenty-four-hour period November 11-12 the fluid intake was 4,950 cc. and the urinary output was 3,170 cc., of which 1,730 cc. drained from the catheter, and 1,440 cc. was voided around it. The urine became relatively clear, containing some red blood cells and a few sulfadiazine crystals. The blood pressure was 140/90. The blood nonprotein nitrogen was 38 mg. per cent and the creatinine 2.4 mg. per cent. The patient's general condition appeared to be improved, although the temperature rose to 103 F. On November 12, another cystoscopy was decided upon to determine the patency of the left ureter.

**Second Cystoscopy.**—The right ureteral catheter was noted *in situ*. The entire bladder mucosa was hyperemic and moderately edematous. The left ureteral orifice was still completely obscured by the bullous edema, and the ureter could not be catheterized.

Intravenous indigo carmine was administered. The dye appeared in good concentration from the right catheter within six minutes. No dye emanated from the left side in thirty-two minutes. The patient was returned with the right catheter still in place.

When the patient was returned to the ward after cystoscopy, his pulse was found to be totally irregular—rate 75, with an irregular apical heart beat of 155. The blood pressure was 115/70. He had, however, no subjective complaints. Auricular fibrillation was diagnosed and confirmed by electrocardiogram. There were no signs of cardiac failure. About four hours after the onset of the fibrillation, the heart suddenly resumed a regular sinus rhythm—84 per minute, with occasional extra-systoles.

The next morning, November 13, the heart was again found to be fibrillating. The blood pressure was 115 systolic and 70 diastolic. An initial test dose of 0.12 Gm. of quinidine sulfate was given orally. About forty-five minutes later, the heart resumed a normal rhythm. Quinidine sulfate, 0.3 Gm. every four hours, was then given as a prophylactic meas-

ure. The following day, a moderate, watery diarrhea developed. The patient complained of giddiness and stated that he had "hot flashes." With the possibility of a toxic effect from the drug in mind, the quinidine sulfate was discontinued. These symptoms cleared quickly and the patient had no further episodes of auricular fibrillation.

The right ureteral catheter was removed during the evening of November 14. It had remained *in situ* for five days.

Throughout the following week the patient's condition continued to improve. The pneumonic process showed signs of resolution, and the fever subsided. The urinary output was maintained satisfactorily, and, microscopically, the urine contained a few pus cells per high-power field. The blood nonprotein nitrogen remained within normal limits.

On November 22, the temperature began to rise. The higher points of the temperature curve coincided with pain in the left flank and the voiding of clear urine; the lower points with relief of pain and the appearance of pus clumps in the voided specimens. Accordingly, on November 25, another cystoscopy was performed.

**Third Cystoscopy.**—The bladder mucosa, although generally mildly hyperemic, appeared much improved. The areas around both ureteral orifices were entirely normal. A 5F catheter was inserted into the easily visible left ureteral orifice for 27 cm. A soft obstruction at 3 cm. was encountered and easily broken up. The urine flow from the left kidney was normal. This urine contained innumerable white cells. The right kidney urine was normal. Cultures of both these urines showed no growth.

Indigo carmine, 5 cc., was given intravenously and appeared on the right side, in good concentration, within five minutes, and on the left side, in equally good concentration, in eleven minutes.

Following the last cystoscopy, the patient became afebrile and remained so. The urine gradually became free of pus cells and sulfadiazine crystals. The specific gravities of casual urine specimens ranged as high as 1.028. The blood nonprotein nitrogen continued to remain within normal limits. The pneumonic process completely resolved, as indicated by physical and x-ray examinations.

On December 12, intravenous pyelography was performed. The right kidney showed good dye concentration, with a bifid pelvis and ureter which united at the level of the third lumbar vertebra. The left kidney revealed a good concentration of the dye, with a normal configuration of the renal calyces, pelvis, and left ureter.

The patient remained asymptomatic and had no complaints. He was discharged from the hospital on December 19, 1942.

## Comment

The toxic symptoms manifested by our patient were: watery diarrhea, abdominal pain, gross and microscopic hematuria, and urinary suppression.

It is a well-established policy that during the administration of a sulfonamide drug, dehydration must be avoided. Our patient did not appear dehydrated on admission. The watery diarrhea, which began about thirty-six hours after the administration of a total dose of 12 Gm. of sulfadiazine, was probably the precipitating factor. In the presence of diarrhea, it becomes imperative to control

it as quickly as possible, and to force fluids adequately

The onset of abdominal pain during the administration of a sulfonamide drug is an indication for careful examination of the urine, and measurement of the fluid intake and output. Should, in addition, diminished urinary output ensue, with or without hematuria, the drug must be discontinued immediately, fluids forced, and cystoscopy performed to determine the patency of the ureters. Any delay may result in aggravation of the pathologic changes in the urinary tract. A marked periureteral edema may occur which may completely obscure the orifice. In addition, the degree of impaction in the ureters may be increased to the extent that it cannot be overcome by catheter manipulation. From the time of the first cystoscopy on November 9 to the third one on November 25 some degree of left ureteral obstruction was present. Had the patency of the right ureter not been established and maintained, it, too, might have become completely occluded, resulting in anuria.

The right ureteral catheter was kept *in situ* for five days. It was removed after it had been ascertained by trial clamping of the catheter, that at least 1,200 cc of urine were being passed around it.

Since the conjugated much more soluble in carbonate was given and was used as an irrigant, administered routinely with a sulfonamide is still a debatable question. Schwartz, Flippin, Reinhold, and Domm<sup>2</sup> studied the urine of 100 patients, one

half of whom were taking sulfathiazole and the remainder sulfadiazine. They concluded that it may be advisable to administer an alkali with these drugs. Others, as does Thompson,<sup>3</sup> question the need for alkalinization, especially when sulfadiazine is used.

### Conclusions

1 Sulfadiazine, notwithstanding the relatively high solubility of its free and acetylated crystals, can produce serious urinary tract complications.

2 A patient receiving this drug should have daily urine examinations and measurement of the urinary output, since serious complications may develop with great rapidity.

3 Any factor producing a sudden dehydration should be combated immediately.

4 A diminishing urinary output associated with a microscopic hematuria warrants immediate withdrawal of the drug. If, in addition, abdominal or flank pain is present, with or without the presence of crystals in the urine, cystoscopy should be performed at once.

5 Any patient who has experienced such toxic renal complications should be thoroughly informed, so that he will be able to give this information, if occasion should arise in which sulfonamides may again be indicated.

### PERSONALITY IN DIAGNOSIS

It has long been an axiom that man produces within himself the maladies that afflict him. For example, there is the mortal whose friends will say of him, after his departure from this vale of tears, "He dug his grave with his teeth." Now medical men are learning to pre-type of ailment persist in being ourselves.

In a new book, *Psychosomatic Diagnosis*, Dr Flinders Dunbar, of this city, explores the relationship between personality and the thousand natural shocks that flesh is heir to. Emotional people tend to suffer from indigestion. Extroverts, with their impulsive and unmethodic natures, are prone to become fracture, contusion, and abrasion cases. takes life seriously quite likely to

More and more the doctor, when Mr Brownley has to go to see him, will want to know, first of all, the sort of person Mr Brownley is. Is Mr B a confirmed misanthrope, with a mean, suspicious reactionary front toward the world? Then the chances are that he has one of the numerous grave disorders listed in the Diagnostician's Desk Manual under Chapter X, and he had better be hospitalized at once for observation.

If, however, his normal disposition is sunny and convivial, if he readily wins friends and influences people, if he sings in the bathtub, then it is a safe assumption that his trouble is listed in Chapter XIII, under Dietary Disorders, and that a couple of good doses of Tinc Slip Ellum at bedtime will fix him up.

Let it not be supposed, however, that it will be as simple as that for the physician of the future. For personalities are not always clear-cut. A man may be both a timid soul and an extremely left-wing liberal. In that case it would be hasty to say, off hand, that his disease is chicken pox. It may rather be scarlet fever. In the same way the affliction of the concealed and extremely busy blowhard may be auto-intoxication, the hives, or pneumonia.

The doctor will have to put him through supplementary tests to find out for sure.

Nevertheless we can believe that the doctor in the primary study of the It will give him's wrong. It will save much time. And from all the gloomy reports nowadays regarding the health of the American people, the doctor of the future is going to need every waking minute for the work on his hands.—Topics of the Times, New York Times, August 10, 1944

# Case Report

## TOTAL PERINEAL PROSTATECTOMY FOR ENDOGENOUS PROSTATIC CALCULI

K. K. NYGAARD, M.D., and E. W. WEBER, M.D., White Plains, New York

FOR many years considerable interest has centered on various phases of prostatic calculi. An excellent up-to-date review has recently been presented by Gutierrez.<sup>1</sup> There probably has been a tendency to underestimate the frequency of these calculi. In a nonselective group of more than 300 autopsies, Randall<sup>2</sup> found prostatic calculi to be present in slightly more than one-fourth of the cases. It is reasonable to expect that this frequency will be found to be higher in autopsy material from men dying of some type of genitourinary pathologic change. Nevertheless, it has been the general impression that, in a routine urologic practice, prostatic calculi do not occur as a frequent urologic problem for the simple reason that a great percentage of prostatic calculi remain "silent" or escape detection. Granted that the basis of the formation of endogenous prostatic calculi, the corpora amylacea, can be considered the result of physiologic processes, there is evidence to indicate that the further formation of calcium salts around these organic nuclei is precipitated by physiopathologic processes. When the formation of calculi is well under way, secondary inflammatory processes develop in the majority of cases. On this basis the endogenous prostatic calculi must be considered a potential source of more serious urologic changes, even though the majority of them during early stages may be considered "silent."

The patient may present himself without symptoms that have any relation to prostatic disease. In three cases reported by Pool and Thompson,<sup>3</sup> attacks of chills and fever constituted the main clinical phenomena. Typical crepitation, felt by palpation of the prostate, appears to be present in about half of the cases. Roentgenograms will reveal the condition in all cases, if precautions are taken to include the pubic region in the examination.

In the presence of prostatic calculi only a careful urologic investigation will furnish sufficient data on which the urologist may base an estimate of the relative role played by the calculi. In many cases the problem of the urologist parallels that of the gastro-enterologist confronted with so-called "silent" gallstones. In such cases nonsurgical treatment, repeated, if necessary, over long periods of time, may satisfactorily improve the inflammatory processes of the prostatic gland.

In other cases of endogenous prostatic calculi the problem may be more complicated and may necessitate some type of surgical intervention. According to Henline,<sup>4</sup> operation is indicated "(1) when obstructive symptoms develop; (2) when malignancy is suspected; (3) when infection sets in causing

severe local urinary disturbance; or (4) when the local infection may be the focus of infection elsewhere in the body."

There is no general agreement concerning the surgical procedure to be employed. The following pathologic findings have been emphasized in determining the type of surgical procedure to be chosen.

The formation of endogenous prostatic calculi is the result of processes taking place in the prostate gland proper. This is in contrast to prostatic adenomas, which are formed from the periurethral glands.

The coexistence of calculi and inflammation makes impossible a clean separation of gland tissue and the prostatic capsule. Coexistence of endogenous calculi and prostatic adenoma does not complicate the technical removal of the adenoma. In the latter cases, however, simple removal of the adenoma through suprapubic or perineal procedures would leave behind the inflamed prostatic tissues together with the majority of the calculi, all pushed to the periphery by the growing adenoma. It is consequently maintained by some workers<sup>4</sup> that only a radical removal of the prostate gland with its calculi and adherent capsule will guard against subsequent reinfection and complicating sequelae. For these reasons total or subtotal perineal prostatectomy has been employed. In 43 cases of total or subtotal perineal prostatectomy Lowsley<sup>5</sup> reports a mortality of 9.3 per cent. This group included operable cases of cancer of the prostate gland as well as prostatic calculi; the fatal cases occurred in the cancer group.

Other observers, representing a less radical view, have reported satisfactory results with perineal prostatolithotomy in cases of noncomplicated prostatic calculi, while simultaneous perineal removal of prostatic adenomata is advocated when the latter and calculi coexist.

From a pathologic point of view there should, a priori, be reason to expect that transurethral prostatic resection and manipulation of endogenous calculi would give the least satisfactory results. Unfavorable results certainly have been reported by some investigators. By others,<sup>3,6</sup> however, remarkable results have been obtained by this transurethral approach, even in cases where the size of the individual calculi might have been expected to prohibit this procedure.

From this brief review it appears at present that there exists no standard method of approach in the surgical treatment of prostatic calculi. This has to be individualized to include the afflicted patient and the existing changes, as well as the individual surgeon.

From the White Plains Hospital, White Plains, New York.

FIG. 2. Sketch of operative findings after separation of the prostatic gland from its apical part.

### Case Report

A man, aged 63 years, for the last ten years had noted moderate frequency of urination. During the last one or two years he had had to arise at night from three to five times, at which times moderate dysuria was noted. At other times more marked dysuria would occur during short-lasting episodes, when he had the impression he was passing gravel with the urine. He had never noted the presence of blood.

On April 1, 1941, he was admitted to the Medical Service of the White Plains Hospital following an attack of pain typical of left renal colic. Physical examination revealed that the patient was in good condition, with moderate peripheral arteriosclerosis.

The blood pressure was 140/90. Manual rectal palpation revealed a rather pronounced enlargement of the prostate. The gland was very tender to direct pressure, but without fluctuating areas indicative of abscess formation. The crepitation typical of prostatic calculi was present. The general physical examination otherwise gave essentially negative results.

The urine contained 35 pus cells per hpf. A great number of residual urine amounting to 28 cc. was found. The flat plate of the abdomen revealed a large, dense, flat plate of the abdomen (Fig. 1). An excretory uro-

contrast The left kidney, however, was markedly reduced in caliber because of per-

patient, as he was excessively sensitive to pain and any type of instrumentation. Simple palpation of the prostate as well as regular catheterization of the bladder brought on episodes of faintness. His

tion when this was suggested to him. This mental attitude of a patient, all too familiar, was sufficiently pronounced in the present case to be taken into consideration when outlining the surgical procedure. In view of the desirability of a complete eradication of the inflammatory processes and the prostatic calculi, it was decided to do a preliminary cystostomy to be followed by subtotal perineal

the pre-  
(K.N.).

The bladder musculature was found to be slightly trabeculated, with moderate hyperemia in the mucosa of the trigone. A small hard stone with sharp surfaces, 3 by 5 mm. in diameter, was removed from the bladder. There was moderate swelling and hyperemia around the left ureteral meatus. A small ureteral catheter was passed up the left ureter to the kidney pelvis without meeting any obstruction, following which a left ureteral dilatation was performed. To the right of the right ureteral meatus was found a small papillomatous growth, covering with its base an area of about 0.5 cm. It was removed down to its base, which was left for subsequent fulguration. The bladder was finally closed around a Pezzet's catheter. Microscopic examination of the removed growth verified the diagnosis of papilloma of the bladder.

During the first few postoperative days the chief difficulty was the patient's mental attitude, which had changed from one of resigned indifference before the operation to one of pronounced apprehension

and restlessness after the operation. After five days, however, he became calmer. The further course was uneventful except for an infection of the upper respiratory tract contracted at the beginning of the second postoperative week which necessitated postponement of the second stage of the procedure.

The latter was performed (K. K. N.) on May 5, 1941, with the patient under spinal anesthesia supplemented by general anesthesia. A perineal approach was employed, essentially following the technic described by Young.<sup>7</sup> Because of marked periprostatis, particularly in the region of the seminal vesicles, the freeing of the prostate on its lateral and posterior aspects was difficult. Following the technic of Henline, the surgeon incised the prostate transversely about 1 cm. proximal to the apex of the gland, cutting through prostatic tissue and the prostatic urethra onto the metal catheter previously introduced through the penile urethra. It was then noted that one large, many-faceted stone, about 0.5 cm. in diameter, and numerous small ones were lodged in the tissues of the apex, giving it a honeycombed appearance and making it unsuitable for anastomosis with the vesical neck. (Fig. 2) After the introduction of Young's prostatic tractor into the prostatic urethra the anterior aspect of the prostate was freed, the bladder opened and cut from the prostate at the vesical neck, and the prostate removed after clamping and ligating the seminal vesicles and the ampullae. The remaining apical part of the prostate was then carefully dissected out, with its enclosed part of the urethra removed down to the beginning of the membranous urethra. A 22 F. rubber catheter was inserted through the urethra. Around this catheter the anastomosis of the vesical neck and the membranous urethra was accomplished without undue tension, using five separate sutures of Number 2 chromic catgut.

In anticipation of reactions from the patient's labile vasomotor system, 500 cc. of blood had been withdrawn before the operation and he was given a transfusion with it during the operation. Another transfusion was given the following day. During the first two days the pulse rate remained at about 120, the temperature 101 to 102 F., with subsequent fall in temperature and pulse. It was interesting to note that, according to the patient, his reaction to the first operation was more serious than to the second one. From the eighth postoperative day the temperature was normal. There was moderate perineal drainage for one week. The urethral catheter was removed after thirteen days,

when the patient was allowed out of bed. From the fifteenth day the suprapubic catheter was clamped, after which time he had normal control of urination except for slight incontinence when arising from a chair. Three weeks after operation the Pezzer's catheter was removed, a cystoscope was introduced into the bladder suprapubically, and fulguration of the base of the bladder papilloma was performed. After another two days the patient left the hospital in good general condition.

A cystoscopic examination under spinal anesthesia on August 22, 1941, revealed no constriction of the urethra or bladder neck. A slight hyperemia of the bladder trigone was noted. Below the right ureteral meatus a recurrent papilloma about 2 mm. in diameter was observed, which was fulgurated.

The patient is now in excellent general condition, and is working full-time as a plumber. He is free of any urinary disturbances. To the patient, the most satisfactory result of the operation has been the disappearance of his previously constant back-ache.

### Comment

No doubt the subtotal prostatectomy, according to the technic of Henline, represents a surgical procedure which accomplishes everything expected of a radical procedure when such is considered indicated, and still satisfactorily avoids the danger of an irreparable lesion of the external sphincter so frequently associated with total perineal prostatectomy. The present case, however, demonstrates that such a subtotal prostatectomy, in the presence of diffuse formation of calculi also in the prostatic apex, necessarily has to be converted into the more complicated procedure of total prostatectomy. This point seems of some significance in considering the surgical approach to be adopted in the individual case.

### ARMY OPENS MALARIA TREATMENT CENTER

The Moore General Hospital, Swannanoa, North Carolina, has been designated a medical center for the study and treatment of tropical diseases, under the command of Lt. Col. Joseph M. Hayman of Cleveland. It was opened on September 1. There are 350 beds in this center for patients who are receiving active treatment, and in addition there are barracks facilities for 1,100 men for the reconditioning program. On release from bed treatment the patients will be transferred to the reconditioning barracks and continue any further treatment

required in addition to the training needed to prepare for active duty again. As far as possible all tropical disease patients in the Army will be concentrated at the new center. Particular attention will be paid to malaria and filariasis. Facilities for expansion of bed capacities as required are being provided. The new center will be under the supervision of Lt. Col. Francis R. Dieuaide, chief of the Tropical Disease Branch of the Medicine Division of the Surgeon General's Office, headed by Brig. Gen. Hugh J. Morgan.—*J.A.M.A.*, Sept. 2, 1944

# Case Report

## SELECTIVE LOCALIZATION OF INSULIN ATROPHY

ANNA R. SPIEGELMAN, M.D., New York City

THE first observations on insulin atrophy were reported by Depisch<sup>1</sup> in 1926. At about the same time Barborka<sup>2</sup> described two cases which occurred at sites continuously used for the injection of insulin. Insulin atrophy has since been reported so frequently that it is accepted as a common complication of insulin therapy. In all of the reports patients exhibiting this form of sensitivity have developed areas of atrophy regardless of the site of the injection. To our knowledge, there has been no report of atrophy occurring at one site but not at another. We thought it of value, therefore, to report such a case of selective localization of insulin atrophy.

### Case Report

Mrs. M. F., 50 years of age, was discovered to be a diabetic by her physician. She had been using for the injections into the thighs. Areas were chosen three to four inches above the parts of the arms already affected. Two injections of protamine zinc insulin were given into the left arm and one into the right arm. All three injections resulted in areas of atrophy.

### Discussion

Marble and Smith<sup>3</sup> have shown that histologic examination of tissue excised from atrophic areas indicates that insulin atrophy is due to the disappearance of fat, seemingly a process of lipolysis, with practically no evidence of inflammatory reaction. The fat which disappears is neutral fat. We may assume, in this patient, that the subcutaneous fat on the arms differs chemically from that on the thighs. This case demonstrates that it might be of

benefit to patients who are subject to insulin atrophy to change the site at which insulin is injected.

## THE PROBLEM OF TUBERCULOSIS IN STATE HOSPITALS

Tuberculosis in state hospitals is a larger problem than has been generally recognized. It is to be expected that 4 per cent of the patients will have active pulmonary tuberculosis. Unless these pa-

tients are found, they constitute a source of contagion to the entire population.—Joseph R. Blalock, M.D., and James B. Funkhouser, M.D., in *Annals of Internal Medicine*, Aug. 1943

# Workmen's Compensation Law

(With Amendments and Annotations to May, 1944)

WE herewith publish Section 13 of the Workmen's Compensation Law as recently amended together with:

(1) Rules of the Medical Appeals Unit of the Industrial Council regulating procedure before the Medical Practice Committee, the Workmen's Compensation Boards, and Committees of the County Medical Societies.

(2) Rules of the Industrial Council governing Appeals and reviews before the Medical Appeals Unit of the Industrial Council.

(3) Rules of Procedure on Arbitration of Medical Bills under Section 13-a(3) and 13-g of the Workmen's Compensation Law.

(4) Article 4-A concerning Silicosis and other Dust Diseases.

(5) Section 1264 of the *Education Law* governing revocation of certificates; annulment of registration for rebating, and splitting of fees, etc.

(6) Section 40 of the *Insurance Law* concerning failure of an insurance carrier to comply with the provisions of the *Workmen's Compensation Law*.

(7) General rules and regulations adopted by the Industrial Commissioner governing Workmen's Compensation Practice.

HARRY ARANOW, M.D., *Chairman*

JOSEPH P. HENRY, M.D.

DAN MELLEN, M.D.

*Council Committee on Workmen's Compensation*

DAVID J. KALISKI, M.D.

*Director of the Bureau of Workmen's Compensation, Medical Society of the State of New York*

## §13. Treatment and care of injured employees.

(a) The employer shall promptly provide for an injured employee such medical, surgical, or other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus <sup>2</sup>for such period as the nature of the injury <sup>3</sup>or the process of recovery may require<sup>4</sup>. The employer shall be liable for the payment of the expenses of medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches, and apparatus, <sup>5</sup>as well as artificial members of the body or other devices or appliances necessary in the first instance to replace, support, or relieve a portion or part of the body resulting from and necessitated by the injury of an employee, for such period as the nature of the injury or the process of recovery may require, <sup>6</sup>and the employer shall <sup>7</sup>also be liable for replacements or repairs of such artificial members of the body or such other devices or appliances <sup>8</sup>necessitated by ordinary wear. Such a replacement or repair of artificial members of the body or such other devices or appliances shall not constitute the payment of compensation under §25-a of this chapter. All fees and other charges for such treatment and services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living.

The commissioner shall prepare and establish a schedule for the state, or schedules limited to defined localities, of minimum charges and fees for such medical treatment and care, to be determined in accordance with and to be subject to change pursuant to rules promulgated by the commissioner. Before preparing such schedule for the state or schedules for limited localities the commissioner shall request the president of the Medical Society of the State of New York to submit to him a report on the amount of remuneration deemed by such society to be fair and adequate for the types of care to be

rendered under this chapter, but consideration shall be given to the view of other interested parties. The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule. Nothing in this schedule, however, shall prevent voluntary payment of amounts higher than the fees and charges fixed therein, but no physician rendering medical treatment or care may receive payment in any higher amount unless such increased amount has been authorized by the employer, or by decision as provided in section thirteen-g herein. <sup>9</sup>Nothing in this section shall be construed as preventing the employment of a duly authorized physician on a salary basis by an authorized compensation medical bureau or laboratory. [This subdivision (a) amended by L. 1922, ch. 615; L. 1935, chs. 258 and 930; L. 1939, ch. 540; L. 1944, ch. 463.]

<sup>1</sup> Subdivision letter "(a)" inserted by L. 1935, ch. 258.

<sup>2</sup> Words "for such period" inserted by L. 1922, ch. 615.

<sup>3</sup> Words "or the process of recovery" inserted by L. 1922, ch. 615.

<sup>4</sup> Words, "during sixty days after the injury; but the commission may where the nature of the injury or the process of recovery requires a longer period of treatment require the same from the employer" as amended by L. 1918, ch. 634, stricken out by L. 1922, ch. 615.

<sup>5</sup> Words "The employer shall . . . §13-g herein" inserted by L. 1935, ch. 258.

<sup>6</sup> Words "as well as . . . resulting from and" inserted by L. 1939, ch. 540.

<sup>7</sup> Words "but the employer. . . or appliances" inserted by L. 1939, ch. 540; word "and" substituted for word "but" by L. 1944, ch. 463.

<sup>8</sup> Sentence "Nothing in . . . or laboratory" added by L. 1935, ch. 930.

<sup>9</sup> Word "also" substituted for word "not" by L. 1944, ch. 463.

<sup>10</sup> Words "necessitated by . . . of this chapter" inserted by L. 1944, ch. 463.

*Fee schedules.* The Commissioner may not prescribe a

minimum fee schedule for hospitals. Opinion of Attorney-General, December 14, 1936.

Pursuant to this subdivision (a), a "Minimum Medical Fee Schedule" which applies to the entire State has been promulgated by the Industrial Commissioner. It is not reproduced here but copies may be obtained from the Department of Labor at nominal cost. Rules and regulations promulgated under §§13-13 j.

(b) In the case of persons injured outside of this State, but entitled under this chapter, the authorized physicians

so at the expense of the employer. The employee shall not be entitled to recover any amount expended by him for such treatment or services unless he shall have requested the employer to furnish the same and the employer shall have refused or neglected to do so, or unless the nature of the injury required such treatment and services and the employer or his superintendent or foreman having knowledge of such injury shall have neglected to provide the same; nor shall any claim for medical or surgical treatment be valid and enforceable, as against such employer, unless within twenty days following the first treatment, the physician giving such treatment, furnish to the employer and the industrial commissioner a report of such injury and treatment, on a form prescribed by the industrial commissioner. The board may, however, by the unanimous vote of all the qualified members, excuse the failure to give such notice within twenty days when it finds it to be in the interest of justice to do so, and may, subject to the limitations contained in §28 of this chapter, make an award for the reasonable value of such medical or surgical treatment. All fees and other charges for such treatment and

of a like standard of living [This subdivision (b) amended by L. 1922, ch 615, L 1927, ch 533; and L. 1935, ch. 253]

by L. 1922, ch. 615

"Sentence" "The board . . . surgical treatment" inserted by L. 1927, ch. 553

"Word "finds" substituted for word "and" by L. 1935, ch. 258.

"Words "whether furnished by the employer or otherwise" inserted by L. 1927, ch 553

"Word "board" substituted for word "commissioner" by L. 1927, ch 553.

Fees—treatment outside State For bills of New Jersey physicians giving medical treatment to residents of New Jersey injured in New York State, see Opinion of Attorney General, July 8, 1936

Medical reports—filing Employers or carriers must promptly file with the commissioner all physician, hospital, or other medical reports coming into their possession. Board's Rules and Procedure, Rules 1 and 2 appended below.

For the report required by this subdivision (b), the Division of Workmen's Compensation of the Department of Labor supplies form C-4

(c) The liability of an employer for medical treatment as herein provided shall not be affected by the fact that his employee was injured through

the fault or negligence of a third party, not in the same employ.<sup>1</sup> The employer shall, however, have an additional cause of action against such third party to recover any amounts paid by him for such medical treatment, in like manner as provided in §29 of this chapter [This subdivision (c) added by L. 1927, ch 553, lettered (c) by L. 1935, ch 258, and amended by L. 1941, ch. 474.]

<sup>1</sup> Subdivision letter "(c)" supplied by L. 1935, ch 258, text supplied by L. 1927, ch 553

<sup>2</sup> Words "unless and until notice of election to sue or the bringing of suit against such third party" eliminated by L. 1944, ch 474

(d) The industrial board, on its own motion, or a referee, upon the recommendation of the chief medical examiner for the workmen's compensation division, hearing a claim for compensation may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed; and may require a report from such physician on the diagnosis, the causal relationship between the alleged injury and subsequent disability, proper treatment, and the extent of the disability of such claimant. The employer or his insurance carrier shall pay for such examination in an amount to be directed by the industrial commissioner.

The industrial commissioner may employ, within the limits of the appropriation therefor, physicians of outstanding qualifications as committees of expert consultants in such fields of medicine as he deems essential in order to ascertain the diagnosis, the causal relationship between the al-

employed by or accept or participate in any fee from any insurance company authorized to write workmen's compensation insurance in this state, or from

of expert consultants shall constitute the findings and opinions of the committee. The contents of such report of the committee of expert consultants when introduced in evidence shall constitute prima facie evidence of fact as to the matter contained therein, and any of the makers of such report shall be subject to examination upon demand. [Added by L. 1935, ch. 258; amended by L. 1941, ch. 465.]

<sup>1</sup> This subdivision "(d)" added by L. 1935, ch 258

<sup>2</sup> Provision that the physician to conduct such examination shall be designated by the commissioner from a panel submitted to him by the county medical society was stricken out by L. 1944, ch 465.

<sup>3</sup> Rest of subdivision added by L. 1944, ch 465.

§13-a. Selection of authorized physician by employee. (1) An injured employee may, when care is required, select to treat him any physician authorized by the commissioner to render medical care, as hereafter provided. If for any reason during the period when medical treatment and care is required, the employee wishes to transfer his treatment and care to another authorized physician, he may do so, in accordance with rules prescribed by the commissioner. In such instance the remuneration of the physician whose services are being dispensed with shall be limited to the value of treatment rendered at minimum fees as established in the schedule for his location, unless payment in higher amounts has been approved as authorized in §13, Paragraph a. <sup>1</sup>If a claimant shall receive treatment in any hospital or other institution operated in whole or in part by the State of New York, the employer shall be liable for food, clothing, and maintenance furnished by the hospital or other institution to such employee. If the employee is unable, due to the nature of the injury, to select such authorized physician and the emergency nature of the injury requires immediate medical treatment and care, or if he does not desire to select a physician, and in writing so advises the employer, the employer shall promptly provide him with the necessary medical care, provided, however, that nothing herein contained shall operate to prevent such employee, when subsequently able to do so, from selecting for continuance of any medical treatment or care required, any physician authorized by the commissioner to render medical care as herein-after provided.

<sup>1</sup> Sentence "If a claimant . . . such employee" inserted by L. 1944, ch. 663.

An employer may maintain a licensed compensation medical bureau, use of which shall be optional with his injured employee: §13-j, subdivision (2), below.

Compare §§13-i, 13-j, and notes thereunder.

*Employee, agent of employer.* An employee exercising his statutory right in choosing a physician does so as agent of the employer and binds the latter for cost of the treatment: *Armstrong v. Weiss and Others*, 168 Misc. 653; 204 S. B. 232.

(2) The commissioner shall prescribe the form of a notice informing employees of their privilege under this chapter, and such notice shall be posted and maintained by the employer in a conspicuous place or places in and about his place or places of business.

The commissioner has prescribed the notice form required by this subdivision (2) to be posted by employers, including self-insurers. It is No. 105. Its size may not be reduced without his consent: Rules of Comr., Rule 20. It contains numbered instructions addressed "To employers" and "To employees." Combined with this posting notice is the posting notice required by §51, below.

To avoid the solicitation banned by §13-i below, the commissioner may so formulate the notice required by this subdivision (2) as to exclude the names of physicians from it: Opinion of Attorney-General, July 8, 1935.

(3) The employer shall have the right to transfer the care of an injured employee from the attending physician, whether chosen originally by the employee or by the employer, to another authorized physician (1) if the interest of the injured employee necessitates the transfer or (2) if the physician has not been authorized to treat injured employees under this act or (3) if he has not been authorized under this act to treat the particular injury or condition as provided by §13-b (2). An authorized physician from whom the case has been transferred shall have the right of appeal to an arbitration committee as provided in subdivision two of §13-g and if said arbitration committee finds that the transfer

was not authorized by this section, said employer shall pay to the physician a sum equal to the total fee earned by the physician to whom the care of the injured employee has been transferred, or such proportion of said fee as the arbitration committee shall deem adequate.

Rules of Procedure governing arbitration appear below, page 2736.

(4) No claim for medical or surgical treatment shall be valid and enforceable, as against such employer, or employee, unless within forty-eight hours following the first treatment the physician giving such treatment furnish to the employer and <sup>2</sup>*directly* to the industrial commissioner a preliminary notice of such injury and treatment, <sup>3</sup>within <sup>4</sup>fifteen days thereafter a more complete report <sup>5</sup>and subsequent thereto progress reports if requested in writing by the industrial commissioner, industrial board, employer or insurance carrier, at intervals of not less than three weeks apart or at less frequent intervals if requested on <sup>6</sup>forms prescribed by the industrial commissioner. The industrial board may excuse the failure to give such notices within the designated periods when it finds it to be in the interest of justice to do so. Upon receipt of the notice herein provided the employer shall be entitled to have the claimant examined by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, and refusal by the claimant to submit to such examination at such time or times as may reasonably be necessary in the opinion of the industrial board, shall bar the claimant from recovering compensation for any period during which he has refused to submit to such examination.

<sup>1</sup> Word "and" eliminated by L. 1940, ch. 542.

<sup>2</sup> Word "fifteen" substituted for word "twenty" by L. 1940, ch. 542.

<sup>3</sup> Words "and subsequent . . . frequent intervals if requested" inserted by L. 1940, ch. 542.

<sup>4</sup> Word "forms" substituted for words "a form" by L. 1940, ch. 542.

<sup>5</sup> Words "directly to" inserted by L. 1944, ch. 472.

All C-4 reports of attending physicians should be verified for evidence purposes: Rules of Commissioner, Rule 4.

Concerning physical examinations, see also §13, subdivision (d) above, and §§19, 19-a, 41; Rules of Board, Rule 11, and Rules of Commissioner, Rule 25.

(5) No claim for specialist consultations, surgical operations, or physiotherapeutic procedures costing more than twenty-five dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. No claim for x-ray examinations or special diagnostic laboratory tests costing more than ten dollars shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency.

(6) *Any interference by any person with the selection by an injured employee of an authorized physician to treat him, and the improper influencing or attempt by any person improperly to influence the medical opinion of any physician who has treated or examined an injured employee shall be a misdemeanor\*.* [Subdivision (6) added by L. 1944, ch. 471.]

[This §13-a added by L. 1935, ch. 258, and amended by L. 1940, ch. 542; L. 1944, chs. 471, 472, 663.]

\* Italics ours.

See also Rules of Industrial Commissioner, relative to authorization, selection, reports and supervision of specialists

§13-b. <sup>1</sup>Medical practice committee, authorization of physicians, medical bureaus, and laboratories by commissioner. 1. <sup>2</sup>The industrial commissioner shall appoint for, and with jurisdiction in, all

bureaus operated by qualified physicians to be authorized to render medical care, and of laboratories and bureaus engaged in x-ray diagnosis or treatment or in physiotherapy or other therapeutic procedures, under this chapter. Each member

ized to write workmen's compensation insurance in this state or from any self-insurer, whether such employment or fee relates to a workmen's compensation claim or otherwise. The attorney general, upon request, shall advise and assist such com-

of such medical practicing a population of one million or more, and in other counties upon the recommendation of the medical society of the county or of a board designated by such county society or of a board representing duly licensed physicians of any other school of medical practice in such county, the industrial commissioner may authorize physicians licensed to practice medicine in the State of New York to render medical care under this chapter. If, within sixty days after the commissioner requests such recommendations in any counties having a population of less than one million, the medical society of such county or board

commissioner, provided, that:

(a) Emergency (first aid) medical care may be rendered under this chapter by any physician licensed to practice medicine in the state of New York without authorization of the commissioner under this section; and

(b) A licensed physician who is a member of a constituted medical staff of any hospital may render medical care under this chapter while an injured employee remains a patient in such hospital; and

(c) under the active and personal supervision

vision shall be evidenced by signed records of instructions for treatment and signed records of the

patient's condition and progress. Reports of such treatment and supervision shall be made by such physician to the commissioner on such forms and at such times as the commissioner may require. [This subdivision 1 amended by L. 1935, ch. 930; L. 1944, ch. 459.]

<sup>1</sup> Sidelittle amended by L. 1944, ch. 459. Formerly read "Authorization of physicians by commissioner."

<sup>17</sup> Word "five" substituted for word "four" by L. 1944, ch. 459.

<sup>18</sup> Word "registered" inserted by L. 1935, ch. 930

2. A physician licensed to practice medicine in

this chapter with the <sup>2</sup>medical practice committee if his office is located in a county having a population of one million or more, or, if his office is located in any other county, with the medical society in such county, or with a board designated by such

tivities under this chapter to such medical care as his experience and training qualify him to render. He shall further agree to refrain from subsequently treating for remuneration, as a private patient, any person seeking medical treatment in connection with, or as a result of, any injury compensable under this chapter, if he has been removed from the list of physicians authorized to render medical care under this chapter, or if the person seeking such treatment has been transferred from his care in accordance with the provisions of this chapter. This agreement shall run to the benefit of the injured person so treated, and shall be available to him as a defense in any action by such physician for payment for treatment rendered by a physician after he has been removed from the list of physicians authorized to render medical care under this chapter, or after the injured person was transferred from his care in accordance with the provisions of this chapter. The <sup>3</sup>medical practice committee, or the medical society or the board designated by it, or the board as otherwise provided <sup>4</sup>under this section, if it deems such licensed physician duly qualified, shall recommend to the commissioner that such physician be authorized to render medical care under this

chapter, and such recommendation and authorization shall specify the character of the medical care which such physician is qualified and authorized to render under this chapter. <sup>12</sup>Such recommendations shall be advisory to the industrial commissioner only and shall not be binding or conclusive upon him. <sup>13</sup>The licensed physician may present <sup>14</sup>to the medical practice committee or to the medical society or board, evidences of additional qualifications at any time subsequent to his original application. If the <sup>15</sup>medical practice committee or the medical society or board fails to recommend to the commissioner that a physician be authorized to render medical care under this chapter, the physician may appeal to <sup>16</sup>the medical appeals unit of the industrial council as provided in <sup>17</sup>subdivision <sup>18</sup>five of §10-a of the labor law. [This subdivision 2 amended by L. 1944, ch. 459.]

<sup>1</sup> Words "an application for authorization under this chapter" inserted by L. 1944, ch. 459.

<sup>2</sup> Words "medical practice . . . county, with the" inserted by L. 1944, ch. 459.

<sup>16</sup> Words "clause (g) of" stricken out by L. 1944, ch. 459.

<sup>17</sup> Word "five" substituted for word "four" by L. 1944, ch. 459.

*Constitutionality.* This subdivision does not violate the Federal or State constitutions nor does it constitute an unlawful delegation of power: *Szold v. Outlet Embroidery Supply Co.*, 274 N. Y. 271, affirming 248 App. Div. 865; 159 Misc. 911; appeal dismissed, 303 U.S. 623; 204 S.B. 235.

Physiotherapist who treated injured employee upon advice of carrier's physician and with carrier's acquiescence must look to the employer and its carrier for payment and may not recover his fee for such treatments from the employee: *Sprague v. Spencer*, 172 Misc. 123; 204 S.B. 242.

A physician not authorized under this §13-b may not recover by legal process his fee for treating an injured employee: §13-f, below; *Szold v. Outlet Embroidery Supply Co.*, 159 Misc. 911; 248 App. Div. 865; 274 N.Y. 271; 275 N.Y. Rep. 542; 303 U.S. 623; 204 S.B. 235.

For bills of New Jersey physicians giving medical treatment to residents of New Jersey injured in New York State, see Opinion of Attorney-General, July 8, 1936.

3. Laboratories and bureaus engaged in x-ray diagnosis or treatment or in physiotherapy or other therapeutic procedures and which participate in the diagnosis or treatment of injured workmen under this chapter shall be operated or supervised by qualified physicians duly authorized under this chapter <sup>1</sup>and shall be subject to the provisions of §13-c of this chapter. The person in charge of diagnostic clinical laboratories duly authorized under this chapter shall possess the qualifications

established by the public health council for approval by the state commissioner of health or, in the city of New York, the qualifications approved by the board of health of said city and shall maintain the standards of work required for such approval. [This subdivision 3 amended by L. 1935, ch. 930; this §13-b added by L. 1935, ch. 258.]

<sup>1</sup> Words "and shall . . . of this chapter" inserted by L. 1935, ch. 930.

Concerning x-ray services and payment therefor, see also Rules of Commissioner.

§13-c. Licensing of compensation medical bureaus<sup>1</sup> and laboratories. <sup>2</sup>1. The commissioner may, upon the recommendation of the <sup>3</sup>medical practice committee in counties having a population of one million or more, and in other counties upon the recommendation of the medical society of <sup>4</sup>the county <sup>5</sup>or of a board as provided in §13-b, authorize and license compensation medical bureaus <sup>6</sup>in such counties <sup>7</sup>operated by qualified physicians wholly or principally for the diagnosis and treatment of industrial injuries or illnesses in respect <sup>8</sup>to which they are authorized to render medical care under this chapter. <sup>9</sup>The commissioner, however, shall not authorize or license more than two such bureaus operated by the same physician. <sup>10</sup>The commissioner may, upon the recommendation of the <sup>11</sup>medical practice committee in counties having a population of one million or more, and in other counties upon the recommendation of the medical society of <sup>12</sup>the county or of a board as provided in §13-b, authorize and license separate laboratories and bureaus engaged in x-ray diagnosis or treatment and clinical diagnosis, or in physiotherapy or other therapeutic procedures, which participate in the diagnosis or treatment of injured workmen under this chapter. <sup>13</sup>The commissioner, however, shall not authorize or license more than two such laboratories or bureaus operated by the same physician. Application for such authorization shall be made on forms to be furnished by the commissioner, and shall disclose in full the nature of the personnel and equipment of such bureaus. <sup>14</sup>If within sixty days after such application has been filed the <sup>15</sup>medical practice committee, medical society, or board refuses or fails to act or refuses to recommend to the commissioner that such license be granted, the applicant may appeal to the <sup>16</sup>medical appeals unit of the industrial council as provided in subdivision <sup>17</sup>five of §10-a of the labor law. Each such bureau <sup>18</sup>or laboratory which receives such authorization shall:

(a) Make reports on its personnel and equipment in such form and at such times as may be required by the commissioner; and

(b) Be subject to inspection by the commissioner <sup>17</sup>or the medical practice committee or the medical society of the county in which such bureau or laboratory is located; and

(c) Pay to the commissioner a license fee of fifty dollars per annum for each office of such bureau, <sup>18</sup>or ten dollars per annum for a separate laboratory. [This subdivision 1 amended by L. 1935, ch. 930; L. 1941, ch. 307; L. 1944, ch. 459.]

<sup>14</sup> Word "that" inserted by L. 1944, ch. 459.

<sup>15</sup> Former paragraph (e) deleted and former paragraph (f) relettered (e) by L. 1944, ch. 459. Deleted paragraph (e) read as follows: "(e) has participated in the division, transference, assignment, rebating, splitting, or refunding of a fee for medical care under this chapter." Compare new paragraph (g).

<sup>16</sup> Word "the" eliminated by L. 1944, ch. 459.

<sup>17</sup> Rest of subdivision added by L. 1944, ch. 459.

**§3.** Any person who violates or attempts to violate, and any person who aids another to violate or attempts to induce him to violate the provisions of paragraph (g) of subdivision two of this section shall be guilty of a misdemeanor. [This subdivision 3 inserted by L. 1944, ch. 459.]

<sup>1</sup> This subdivision 3 inserted by L. 1944, ch. 459.

**§4.** Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, either before or after investigation by the medical practice committee or a medical society or board as herein provided, or to temporarily suspend the authorization of any physician that he may believe to be guilty of such misconduct. [This subdivision 4 numbered and amended by L. 1944, ch. 459; this §13-d added by L. 1935, ch. 258.]

<sup>1</sup> Number "4" inserted by L. 1944, ch. 459.

<sup>2</sup> Words "the medical practice committee or" inserted by L. 1944, ch. 459.

For cases involving removal of physicians from list of those authorized to treat workmen's compensation cases, see *Matter of Sacharoff*, 44 N.Y.S. 2d 117, and *Somberg v. Miller*, 266 App. Div. 328.

**§13-e.** Revocation of licenses of compensation medical bureaus. The commissioner may revoke the license of any compensation medical bureau upon a finding certified to him by the medical practice committee, or by a medical society, or by a board designated by such medical society or otherwise, as provided under §13-b, that has recommended the licensing of such compensation medical bureau, or by the medical appeals unit of the industrial council, that such bureau has been guilty of professional or other misconduct, or of violation of the provisions of this chapter, or that the personnel of such bureau is not properly qualified under this chapter, or that the equipment of such bureau is inadequate for the proper rendering of medical care.<sup>10</sup>

<sup>11</sup>The medical appeals unit of the industrial council of the department may review the determination of such medical practice committee, medical society, or board, and on application of the compensation medical bureau accused must do so, and may reopen the matter and receive further evidence. The decision and recommendation of the medical appeals unit of the industrial council shall be advisory to the industrial commissioner, and shall not be binding or conclusive upon him.

The medical appeals unit of the industrial council shall prescribe the rules of procedure governing the investigation, hearing, and determination of all charges of professional or other misconduct under this section.

Nothing in this section shall be construed as limiting in any respect the power or duty of the commissioner to investigate instances of misconduct, or violations of the provisions of this chapter, or violations of rules promulgated by the industrial commissioner under the provisions of this chapter, or failure to submit full and truthful medical reports directly to the industrial commissioner within the time limits provided under subdivision four of §13-a of this chapter, either before or after investigation or hearing by the medical practice committee, or by a medical society or board, or review by the medical appeals unit as herein provided, and to temporarily suspend the license of any laboratory or employer's medical bureau, or after a hearing to revoke the same. [This §13-e added by L. 1935, ch. 258; amended by L. 1941, ch. 307; L. 1944, ch. 459.]

<sup>11</sup> Words "or after a hearing revoke the same" inserted and words "that he may believe to be guilty of such misconduct" eliminated by L 1941, ch 307.

<sup>12</sup> Word "to" inserted by L 1944, ch. 459.

of this chapter to render medical care under this

ant, shall collect or receive a fee from such claimant within this state, but shall have recourse for payment of services rendered only to the employer under the provisions of this chapter. Hospitals shall not be entitled to receive the remuneration paid to physicians on their staff for medical and surgical services.

(2) Whenever his attendance at a hearing is required, the physician of the injured employee shall be entitled to receive a fee from the employer, or carrier, in an amount to be fixed by the industrial board in addition to any fee payable under §120. [This §13-f added by L. 1935, ch. 258; and amended by L. 1940, ch. 60.]

<sup>1</sup> Words "industrial board" substituted for word "commissioner" by L. 1940, ch. 60.

Concerning payment of bills for x-ray and other consultants, see Rules of Commissioner, Rules 7, 9, 13 and 22. Medical laboratories. Lawfully qualified medical laboratories may submit bills for services. Opinion of Attorney-General, May 26, 1936.

Municipal hospitals. The Department of Hospitals of the City of New York is entitled to the fee for services rendered in emergency cases. Opinion of Attorney-General, April 10, 1936.

Physiotherapists. Payment of fees of a physiotherapist figured in *Sprague v. Spencer*, 172 Misc 123, 204 S.D. 242. Unauthorized physicians. A physician not authorized under §13 b, above, may not recover his fee for treating an injured employee. *Sault v. Outlet Embroidery Supply Co.*, 159 Misc. 911; 248 App. Div. 805, 274 N.Y. 271, 275 N.Y. Rep. 542, 303 U.S. 623; 204 S.D. 235.

Witness fees. Fees for appearance and testimony are payable by the employer or carrier even if the claim is found to be not compensable. Opinion of Attorney-General, March 3, 1937.

§13-g. Payment of bills for medical care. (1) Unless within thirty days after a bill has been ren-

dered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such physician or hospital shall be deemed to be the fair value of the services rendered by him or it.

(2) If the parties fail to agree as to the value of medical aid rendered under this chapter to a claimant residing in a county having a population of one million or more, such value shall be decided by the medical practice committee, and in other cases it shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the county in which the claimant resides, two physicians who are members of the Medical Society of the State of New York, appointed by the employer or carrier, and one physician, also a member of the Medical Society of the State of New York, appointed by the industrial commissioner. The majority decision of any such committee shall be conclusive upon the parties as to the value of the services rendered. If the physician whose charges are being arbitrated is a member in good standing of the New York Osteopathic Society or the New York Homeopathic Society, the members of such arbitration committee to be appointed in any county having a population of less than one million shall be physicians of such organization and the president of such organization shall make the designation provided herein.

<sup>1</sup> Words "to a claimant . . . million or more" inserted by L 1944, ch. 467.

<sup>2</sup> Words "by the medical . . . be decided" inserted by L 1944, ch. 467.

<sup>3</sup> Word "and" eliminated by L 1944, ch. 467.

<sup>4</sup> Words "who are" inserted and word "also" eliminated by L 1944, ch. 467.

<sup>5</sup> Words "and one physician . . . by the industrial commissioner" inserted by L 1944, ch. 467.

<sup>6</sup> Words "any such" substituted for words "the arbitration" by L 1944 ch 467.

<sup>7</sup> Sentence "In the event of equal division, the committee shall select a fifth physician, also a member of the medical society of the state of New York, whose decision shall be conclusive" eliminated by L 1944, ch. 467.

<sup>8</sup> Words "in any . . . one million" inserted and word "similarly" eliminated by L 1944, ch. 467.

(3) The parties to arbitration proceedings under this section shall each pay to the industrial commissioner a sum equal to five per centum of the amount payable under such decision, or a minimum

transferred to the state treasury to reimburse it on account of the expense of administering this chapter.

<sup>1</sup> Words "in counties having a population of less than one million" inserted by L 1944, ch. 467.

<sup>2</sup> Words "and in all . . . this chapter" inserted by L. 1944, ch. 467.

(4) In claims where the employer has failed to secure compensation to his employees as required by §50 of this chapter, the board may make an award for the value of medical services or treatment rendered to such employees, in accordance with the schedule of fees and charges prepared and established under the provisions of §13-a of this chapter. Such

award shall be made to the physician or hospital entitled thereto. A default in the payment of such award may be enforced in the manner provided for the enforcement of compensation awards as set forth in §26 of this chapter.

In all cases coming under this subdivision the payment of the claim of the physician or hospital for medical or surgical services or treatment shall be subordinate to that of the claimant or his beneficiaries. [This §13-g added by L. 1935, ch. 258; and amended by L. 1940, ch. 542; L. 1944, ch. 467.]

<sup>1</sup> Subdivision (4) added by L. 1940, ch. 542.

*Failure to request timely arbitration.* A physician brought an action at law for amount due for services rendered to employee of defendant employer injured in an industrial accident. Said employer had made no demand on the Industrial Commissioner for examination of the fairness of the amount claimed until more than sixty days had elapsed after rendition of the bill. The physician refused to submit his bill to arbitration contending the right to such relief had expired at the end of thirty days. Judgment for plaintiff upheld. *Raisman v. Ashford Roofing Co., Inc.*, 261 App. Div. 782.

*Hospital bills.* The arbitration provisions of this section apply to hospitals as well as to physicians: *Reddy v. Pegram*, 169 Misc. 841; 204 S.B. 244.

Arbitration provisions relative to payment of disputed medical bills are not in conflict with New York City Charter: Opinion of Attorney-General, March 10, 1938.

§13-h. Medical treatment by 'hospitals. Hospitals maintained wholly by public taxation may treat only emergency cases under this chapter, and may treat such emergency cases only so long as the emergency exists; <sup>2</sup>provided, however, that <sup>3</sup>this section shall not be applicable, where there is not available a hospital other than a hospital maintained by taxation, nor shall it prevent any municipal, county, or state hospital from rendering medical services to employees of such hospital or such political subdivision. <sup>4</sup>This section shall not apply to cases arising under article 4-A of this chapter; nor to any case where the employer or carrier refuses or neglects to authorize any hospital services that may be required under this chapter after the employee shall have requested the employer or carrier to furnish the same, or when the nature of the injury required such services and the employer or his superintendent or foreman having knowledge of such injury shall have neglected to provide the same, in such cases the injured employee may select any hospital for care and treatment in accordance with this chapter and the rules prescribed by the commissioner. [This §13-h added by L. 1935, ch. 258; amended by L. 1940, ch. 548; L. 1943, ch. 442.]

<sup>1</sup> Word "public" stricken out by L. 1943, ch. 442.

<sup>2</sup> Words "provided however, that this section shall not apply to cases arising under article 4-A of this chapter" inserted by L. 1940, ch. 548.

<sup>3</sup> Words "this section shall not apply to cases arising under article 4-A of this chapter" stricken out by L. 1943, ch. 442.

<sup>4</sup> Remainder of this section added by L. 1943, ch. 442.

Concerning copies of records, duration of emergency status, and identification of insurance company visitants in hospital cases, see Rules of Commissioner, Rules 5, 15, and 16.

§13-i. Solicitation prohibited. Any person who shall make it a business to solicit employment for any person authorized by this chapter to render medical care to an injured employee in connection with any claim under this chapter, shall be guilty of a misdemeanor, except that the employer shall have the right subject to regulations prescribed by the commission, to recommend to the injured employee the names of enrolled physicians who he be-

lieves to be competent to treat him. [This §13-i added by L. 1935, ch. 258.]

Rules of Commissioner, Rule 19, prohibits advertising of any nature on compensation work.

Concerning prosecutions under this §13-i, see Opinions of Attorney-General, November 7, 1935, and September 20, 1937.

*Solicitation construed.* For rules regarding supplying of names of authorized physicians by carriers to their policyholders and procedure to be followed by medical inspectors and consultants engaged by insurance carriers and employers, see Opinions of Attorney-General, August 10, 1936, and May 19, 1937. The permission to recommend a physician is granted to the carrier only where the employee has waived his right or is unable to exercise it: Opinion of Attorney-General, May 14, 1936. Compare 13-a, above, and §13-j, immediately following.

§13-j. Medical or surgical treatment by insurance carriers and employers. (1) An insurance carrier shall not participate in the treatment of injured workmen, except, that it may employ medical inspectors to examine compensation cases periodically, while under treatment, and report upon the adequacy of medical care, and other matters relative to the medical conduct of the case, <sup>1</sup>a copy of which report shall be filed directly with the industrial commissioner within ten days, <sup>2</sup>and that it may maintain rehabilitation bureaus operated by qualified physicians if authorized by the commissioner in accordance with §13-c of this chapter. (2) An employer may maintain a compensation medical bureau at the place or places of employment, if such bureau is required because of the nature of the industrial hazards, or the frequency of injuries to employees arising out of industry. Such bureau or bureaus shall be authorized and licensed pursuant to §13-c, and their use by an injured employee shall be optional in accordance with the provisions of §13-a. [This §13-j added by L. 1935, ch. 258; and amended by L. 1935, ch. 930; L. 1944, ch. 468.]

<sup>1</sup> Words "a copy . . . ten days" inserted by L. 1944 ch. 468.

<sup>2</sup> Words "and that . . . of this chapter" inserted by L. 1935, ch. 930.

#### General Notes on §§13-13-j

*Other provisions governing medical care.* For provisions of the Workmen's Compensation Law governing medical care and treatment additional to those of these §§13-13-j, see §§12, 19, 19-a, 19-b, 25-a, 29, 33, 41, 91, and 124; for supervisory organization and powers of the Industrial Council relative to medical practice and practitioners, Labor Law, §10-a.

*History.* For history of the radical amendment of this §13 and the addition of the ten new §§13-a to 13-j, following, by L. 1935, chs. 258 and 930, see Governor's Message (1934) 184 S.B. 43, and Reports of Physician Committees, N.Y. Legislative Documents (1932) No. 83 and (1934) No. 75. An attack upon the constitutionality of these 1935 medical practice amendments was successfully combated by New York courts and dismissed by the U.S. Supreme Court because no substantial federal question was involved: *Sold v. Outlet Embroidery Supply Co.*, 303 U.S. 623; 274 N.Y. 271; 248 App. Div. 865; 204 S.B. 235. For court interpretation of §13, as it read prior to amendment in 1935, see 162 S.B. 108-111, and 185 S.B. 18-42; for review of the operation of it by the Industrial Commissioner, see Bulletin No. 577, U.S. Bureau of Labor Statistics (1933), pages 27-49.

*Claim filing and notice of accident as affecting liability for medical treatment.* An employer is not liable for medical care and treatment if claim for compensation according to §28 has not been made: *Staff v. Eagle Warehouse & Storage Co.*, 30 S.D.R. 326; 209 App. Div. 307; 133 S.B. 170; or if notice of accident according to §18 has not been given: *Schultz v. Flexlume Corp.*, 230 App. Div. 748; 185 S.B. 26.

*Housekeeping and other expenses necessitated by accident-carrier's liability.* The Industrial Board made award for services of a housekeeper necessitated by an accident: *Kuinkowski v. Lustrader Construction Co.*, affirmed, 214 App. Div. 741; 140 S.B. 121; and for artificial milk for an infant

necessitated by accidental impairment of a mother's lactation: *Moore v. Matland Estate*, 32 S D R 409, 140 S B 120.

*Liability for disability period preceding herniotomy.* Liability for disability period dating from an employee's incurment of hernia until operation was performed three months later was charged against the employer and its carrier where the operation was recommended by a physician two days after the accident but the employer failed to provide it until directed so to do by the Department of Labor. *Shades v. McCloskey & Co.*, 259 App Div 766, 204 S B 234.

*Malpractice.* The Court of Appeals held that the amount collected by an injured employee from a physician for malpractice in treating him for his injury was an offset against the compensation provided by the Workmen's Compensation Law: *Parchefsky v. Kroll Bros*, 267 N Y 410, 185 S B 369.

State employee who suffered injury in course of her employment and subsequent aggravation thereof by faulty diagnosis of a doctor in the same employ contained that she had two remedies: (1) to claim workmen's compensation for her initial injury only and (2) to pursue a claim against the State for its alleged negligence in the diagnosis and treatment of her injury. Held, that the alleged negligence and/or malpractice on the part of the State may be separated from the original injury. *Robison v. State of New York*, 176 Misc 73, 263 App Div 240, 214 S B 159.

*Medical expenses—imitations.* The \$5,000 and \$4,000 compensation maximums of §§15, subdivisions 2 and 5, for temporary disability do not limit the liability of employers for medical expenses nor does the liability of an employer or carrier for medical treatment and care terminate with the end of the compensation period. *Lawrence v. N Y Butchers Dressed Meat Co.*, 266 N Y. Rep. 425, 13 Ind Bul 334.

#### RULES AND PROCEDURE

(Promulgated by the Industrial Commissioner of the State of New York pursuant to Chapter 258 of the Laws of 1935, as amended to August 15, 1941.)

**NOTE.—Rules 1 and 2 have been superseded by the "Rules of the Industrial Council Regulating Procedure before Medical Societies or Compensation Boards of Medical Societies, and before the Industrial Council under §§13-b and 13-d of the Workmen's Compensation Law and §10-a of the Labor Law."**

3. When a physician in association or in co-partnership with another physician or physicians, or through another physician or physicians as employers or agents, maintains and operates one or more offices principally for the treatment of injured claimants under the Workmen's Compensation Act, he shall apply for a compensation medical bureau license.

4. All reports, except Forms C-104 and C-14, shall be submitted to the Industrial Commissioner and the attending physician.

5. The attending physician and one to the employer or insurance carrier. If the specialist acts as attending physician he shall file C-104, C-4, and C-14 reports with the insurance carrier (or with the employer when the carrier is unknown) and with the Industrial Commissioner.

he must secure authorization from the employer or

perform such services.

If telephone request for such authorization is made, it should be confirmed by letter. If such authorization is not forthcoming or is not denied within five working days, or if such denial is not justified medically or otherwise, the special services required for the patient's welfare should be proceeded with on the ground that authorization has been unreasonably withheld.

Such authorization is not required in an emergency. The \$13-a-5 employer for the services \$25 fee applies only to the necessity for such services, but the choice of the specialist is entirely within the jurisdiction of the injured worker.

9. When it is in the interest of the injured employee, and where an x-ray is required and it is impossible to secure the services of a qualified x-ray

ever, shall render a bill for such service to the employer. This in no way, however, deprives the employer or insurance carrier from having other x-ray pictures taken if they so desire.

10. A physician authorized to treat workmen's compensation cases, when requested to supersede another physician, must, before beginning treatment

care of the case and state the reason therefor. If the second physician cannot contact the attending physician, and the claimant's condition requires immediate treatment, the said physician should be in attendance within

case

11. In the event of a serious accident requiring immediate emergency medical aid, an ambulance or any physician may be called to give first-aid treatment.

12. A registered physiotherapist may treat workmen's compensation cases at his own office or bureau when the case is referred to him by an authorized physician. The authorized physician should, however, give written directions to the physiotherapist as to the kind of treatment to be rendered and the number of treatments to be given. These directions must be given in writing by the physician and shall constitute a part of the record of the case.

13. The attending physician or the employer or insurance carrier shall be in attendance within the time specified by the physician in attendance.

14. Physicians treating claimants in hospitals may secure the signature of claimant for authoriza-

tion to obtain copies of any necessary hospital records.

15. The physician in attendance in public hospitals must be the judge as to when the "emergency status" of the case has terminated. In case of a dispute the matter shall be referred to the Compensation Board of the Medical Society of the county in which the hospital is located, for immediate decision.

16. Medical inspectors of insurance companies shall be admitted to hospitals or other institutions where injured employees are confined, upon proper identification, for the purpose of complying with §13-j.

17. Hospitals and dispensaries shall not operate a medical bureau or clinic for the purpose of rendering medical care and treatment to compensation cases.

Hospitals and dispensaries shall not render medical care and treatment to ambulatory compensation cases except for the emergency treatment.

18. No license is required for an employer to operate a first-aid station for emergency treatment, but no subsequent treatments are to be rendered by any one, other than a qualified physician on the minimum fee schedule basis.

19. No advertising matter of any nature on compensation work, by or on behalf of authorized physicians, medical bureaus, or laboratories shall be permitted.

20. No insurance company or self-insurer may reduce the size of NOTICE TO EMPLOYEES (FORM C-105) which is to be posted in all places of employment covered by the Act, unless such permission is granted on application to the Industrial Commissioner.

21. A physician who testifies at hearings or examines claimants or participates in examinations for evidential material for compensation-case hearing purposes only, may accept fees for such services from claimants, employers, or carriers.

22. Hospitals shall render bills for board and room accommodations, medical and surgical supplies, and nursing facilities. Hospitals may render bills for x-ray, physiotherapeutic, anesthesia, and pathologic services when rendered by or under the supervision of salaried physicians on the staff. The names and qualifications of all physicians and persons rendering services for which charges are made by hospitals must be included in all bills and all medical and x-ray reports shall be promptly filed with the employer or its insurance carrier and the Department of Labor.

#### **Rules Governing Recommending of Authorized Physicians by Insurance Carriers and Employers and the Procedure to Be Followed by Medical Inspectors and Consultants**

23. The supplying of names of authorized physicians by insurance carriers to their policyholders is in contravention to §13, as amended by Chapter 253 of the Laws of 1935. Such policyholders and all employers may secure a list of all authorized physicians in the vicinity of their places of business by applying to the Industrial Commissioner of the Department of Labor.

24. Any physician who acts in the capacity of medical inspector for an insurance carrier or employer in the case of an injured employee under the care of another physician shall not participate in the treatment of said injured employee except in

the operation of a rehabilitation clinic or bureau under §13-j of the law. Nothing herein contained affects the right of transfer as provided in §13-a(3).

25. When a medical examination is had under §13-a(4) it shall be by a qualified physician at a place reasonably convenient to the claimant and in the presence of the claimant's physician, if in the latter's opinion his presence is necessary. A duplicate copy of all notices of request for examinations must be sent to the attending physician.

26. No physician designated by an insurance carrier or an employer as a consultant in the case of an injured employee shall subsequently participate in the medical or surgical care of said injured employee, except with the written consent of the injured employee and his attending physician. Nothing herein contained affects the right of transfer as provided in §13-a(3).

#### **Rules Governing the Licensing of and Operation of Compensation Medical Bureaus**

27. The character and frequency of accidents, the number of employees in a given plant and the availability of qualified medical care in the immediate vicinity of the place of employment should be considered in relation to the authorization of an employer's compensation medical bureau.

28. The bureau should be located in the industrial plant or in the immediate vicinity.

29. The question of the necessity of the presence of a physician during working hours, or the availability of a physician at stated hours should be determined by an inspection of the plant to ascertain the nature of the hazards and the frequency of accidents.

30. The bureau shall be well housed with sufficient space, light, and air and shall conform to reasonable sanitary requirements. Proper facilities in the form of personnel for assistance in emergencies, instruments, sterilizers, dressings, drugs, shall be available at all times and in amounts proportionate to the size of the plant and the number of employees. Such facilities shall be adequate for more than mere emergency care and for the more severe type of industrial injury.

31. A bureau license may be given for a stated project which, because of the hazards of the project and the frequency of accidents, requires continued medical care and such license shall be for the life of the given project only. In such cases all employees of all subcontractors shall be covered by the license.

32. No license shall be issued to an employer to cover any but his own employees except as indicated in Rule No. 31.

33. First-aid stations—No license is required to operate a first-aid station by an employer of labor. Such first-aid or emergency station should be properly equipped for first aid in accordance with the type of hazard encountered at the particular place of employment.

34. Form C-105, a notice of the rights of an injured employee and the responsibilities of the employer, shall be posted in each compensation medical bureau and first-aid station.

35. All compensation medical bureaus when operated by summer camps and other institutions, wherein such camps and institutions are operating for a profit, shall be charged a license fee of \$25 per annum for the operation of such medical bureaus which are in operation for six months of the year or less.

Rules of the Medical Appeals Unit of the Industrial Council Regulating Procedure Before the Medical Practice Committee, the Workmen's Compensation Boards and Committees of the County Medical Societies Under §§13 to 13-j, Inclusive, of the Workmen's Compensation Law and §10-a of the Labor Law

1. A. Applications in counties having a population of a million or more, by a duly licensed physician of the State of New York to practice under the Workmen's Compensation Law, or for rerating thereunder, shall be made upon an application form furnished by the Department of Labor which shall be filed at the office of the Medical Practice Committee, 50 Centre Street, Borough of Manhattan, City of New York.

B. Applications in all other counties, by a duly licensed physician of the State of New York to practice under the Workmen's Compensation Law, or for rerating thereunder, shall be made upon a form furnished by the Department of Labor which shall be filed with a Workmen's Compensation Board, or Committee of the County Medical Society.

... million  
... compensation  
... medical bureaus or laboratories operated by  
qualified physicians to render medical care, and such  
other laboratories and bureaus under this chapter  
shall be filed in the office of the Medical Practice  
Committee at 50 Centre Street, Borough of Manhat-

... Medical Practice Committee or the Workmen's Compensation Board, or Committee of the County Medical Society, shall notify the  
... Thereafter, the  
... days from date of  
mailing of such notice of refusal within which to appeal  
to the Medical Appeals Unit of the Industrial Council.

4. Upon the filing of such application or applications, the Medical Practice Committee or the Workmen's Compensation Board, or Committee of the County Medical Society, shall investigate and pass

from such neglect or failure to act, to the Medical Appeals Unit of the Industrial Council.

5. In any investigation or hearing conducted before the Medical Practice Committee or the Work-

(i) The accused physician, medical bureau, or laboratory shall be given thirty (30) days' notice in writing, containing a brief statement of the charge

or charges against such physician, medical bureau, or laboratory, and the time when and place where such charge or charges will be heard. Such notice shall be served either personally or by mail. At least ten

... notice, the  
... laboratory  
... Medical Practice Committee or Compensation Board, or Committee of the County Medical Society, whichever the case may be, answering the charges contained therein.

(b) On the hearing of such charge or charges the accused physician, medical bureau, or laboratory shall be entitled to be represented by counsel and cross-examine witnesses and a stenographic record of the proceeding shall be made. Pursuant to authority of the Medical Practice Committee or the Workmen's Compensation Board, or Committee of the County Medical Society, whichever the case may be, such witnesses shall be placed under oath.

(c) A copy of the record of the proceeding shall be submitted to the Industrial Commissioner, along with the report, findings, and recommendation of the Medical Practice Committee, or Compensation Board, or Committee of the County Medical Society.

(d) Simultaneously, the Medical Practice Committee or Compensation Board, or Committee of the County Medical Society which heard such

tory.

(e) Within thirty (30) days after the service of a copy of the report, findings and recommendations of the Medical Practice Committee, Compensation Board, or Committee of the County Medical Society, as aforesaid, the accused physician or medical bureau may file an appeal therefrom with the Medical Appeals Unit of the Industrial Council by serving a written notice of appeal personally or by mail upon both

Unit of the  
Centre Street  
York, and  
Compensation Board, or Committee of the County Medical Society from whose report, findings, and recommendation the appeal has been taken. Where the report, findings, and recommendations from which an appeal is taken were made prior to June 1, 1914, the period of appeal shall be thirty (30) days from the date of the adoption of these rules, to wit, for a period of thirty (30) days from

6.  
term  
charge  
by sec.  
address

Medical Appeals Unit, or the Department of Labor and received prior to the effective date of these rules shall be deemed due compliance therewith.

7. The Medical Practice Committee or the Workmen's Compensation Board, or Committee of the County Medical Society conducting a hearing shall not be bound by common law or statutory rules of evidence or by technical or formal rules of procedure, except as provided herein; but may make such investigation or inquiry or conduct such hearing in such manner as it deems advisable and necessary in the premises.

8. The Medical Practice Committee shall consist of three members, two of whom shall constitute a

quorum and may proceed with the transaction of such business as may come before them and a decision by a majority of the Committee shall be deemed the decision of the entire Committee.

9. The Industrial Commissioner shall designate a member of the Medical Practice Committee as chairman and shall also appoint a secretary to such committee.

**Rules of the Industrial Council Governing Appeals and Reviews Before the Medical Appeals Unit of the Industrial Council Pursuant to §§13 to 13-j, Inclusive, of the Workmen's Compensation Law and §10-a of the Labor Law**

1. Immediately upon receipt of a notice of appeal or application for review, the secretary of the Medical Appeals Unit shall promptly acknowledge receipt thereof by letter to the appellant or his attorney.

2. Within thirty (30) days after the service of a copy of the report, findings, and recommendations of the Medical Practice Committee, Workmen's Compensation Board, or Committee of the County Medical Society, as provided under the rules governing the Medical Practice Committee, the Workmen's Compensation Board, or Committee of the County Medical Society, the physician, medical bureau, or laboratory may file an appeal therefrom with the Medical Appeals Unit of the Industrial Council by serving a written notice of appeal, personally or by mail, upon both the secretary of the Medical Appeals Unit of the Industrial Council at his office, No. 80 Centre Street, Borough of Manhattan, City of New York, and upon the Medical Practice Committee, or Compensation Board, or Committee of the County Medical Society from whose report, findings, and recommendations the appeal has been taken. Where the report, findings, and recommendations of which an appeal is taken were made prior to June 1, 1944, the time within which said notice of appeal shall be filed with the Medical Appeals Unit of the Industrial Council shall be extended for a period of thirty (30) days from the date of adoption of these rules, to wit, for a period of thirty (30) days from July 19, 1944.

3. The notice of appeal or request for review (both terms are used interchangeably) shall state the charges or the reasons upon which the appeal is based.

A notice of appeal in letter or legal form addressed to the Industrial Commissioner, the Medical Appeals Unit, or the Department of Labor and received prior to the effective date of these rules shall be deemed due compliance therewith.

4. Upon the record of the Medical Practice Committee, Workmen's Compensation Board, or Committee of the County Medical Society and on the briefs when submitted by appellant, the Medical Appeals Unit of the Industrial Council may affirm, reverse, or modify the report, findings, and recommendations of the Medical Practice Committee or the Workmen's Compensation Board, or Committee of the County Medical Society from which such an appeal or review is taken.

5. In its discretion and in furtherance of justice, the Medical Appeals Unit may permit oral argument or receive additional evidence and testimony.

6. Where oral argument or the taking of additional evidence and testimony is directed, the Medical Appeals Unit shall fix a time and place for such hearing for the taking of testimony, and notice thereof by mail shall be given to the appellant or his attorney if there is an appearance by an attorney, and to the Medical Practice Committee or the Workmen's Compensation Board, or Committee of the

County Medical Society, whichever the case may be from whose findings and recommendation an appeal was taken.

7. In appeals where the Medical Appeals Unit permits oral argument or the taking of additional evidence or testimony, any one or all of the members of the Medical Appeals Unit may hold the hearing and receive such further oral argument and such further evidence and testimony as is deemed necessary. A stenographic record of such oral argument, testimony, and evidence shall be made and when transcribed shall be filed with and become part of the record of the case on appeal or review and thereupon the full Medical Appeals Unit shall make its decision and recommendation thereon.

8. In all its hearings and proceedings the Medical Appeals Unit shall not be bound by common law or statutory rules of evidence or by technical or formal rules of procedure but may make such investigation or inquiry or conduct such hearing in such manner as it deems advisable and necessary in the premises.

9. In arriving at a determination, a decision concurred in by two (2) of the three members of the Medical Appeals Unit shall be binding upon and constitute the decision of the Medical Appeals Unit.

10. Until final action is taken by the Industrial Commissioner on the findings and recommendations of the Medical Practice Committee, the Workmen's Compensation Board, or Committee of the County Medical Society or the Medical Appeals Unit of the Industrial Council, the appellant physician, medical bureau, or laboratory may continue in the practice of his profession or the conduct of the business of said bureau or laboratory under the Workmen's Compensation Law, unless otherwise directed by the Industrial Commissioner pursuant to §13-d of the Workmen's Compensation Law.

**Rules of Procedure on Arbitration of Medical Bills Under §§ 13-a (3) and 13-g of the New York Workmen's Compensation Law**

**Abbreviations:**

"Commissioner" refers to the Industrial Commissioner of the State of New York.

"Labor Department" refers to the Department of Labor of the State of New York.

"Medical Society" refers to the appropriate County Medical Society, unless the claimant physician is an osteopath, in which case "Medical Society" refers to the New York State Osteopathic Society, Inc.

"Carrier" refers to the employer or his insurer.

"Rating Board" refers to the Compensation Insurance Rating Board.

In cases where the claimant physician and carrier fail to agree as to the value of medical aid rendered under the Workmen's Compensation Law to an injured employee residing in a county having a population of one million or more, such value shall be decided by the Medical Practice Committee as provided in §13-g of said Law.

In cases where the claimant physician and carrier fail to agree as to the value of medical aid rendered under the aforesaid Law to an injured employee residing in a county having a population of less than one million the procedure as respects arbitration shall be as follows:

**PROCEDURE**

1. **Initiating arbitration.** On receipt of a medical bill which is regarded as unfair, notice of any ob-

jection thereto shall be given by the carrier in accordance with §13-g (1) within thirty days after receipt of the bill on a form approved for this purpose. The original is to be mailed to the Commissioner and copies thereof shall be sent to the claimant physician, Medical Society, and Rating Board. The copies to the claimant physician and Rating Board shall be accompanied by the Submission, as provided in Rule 5 herein. The notice shall briefly state all objections to the bill. In cases where there

tested by the carrier, by filing a request for such arbitration with the carrier, Medical Society, Rating Board, or Labor Department. Upon notification of the receipt of such request, the carrier shall promptly proceed in accordance with the requirements of Rule 5 herein.

An "authorized" physician claiming that a case has been as provided proved from copies thereof and carrier.

2. A copy of the bill shall be sent to the carrier, Medical Society, and Rating Board.

3. Selection of arbitrators. In accordance with §13-g (2) an arbitration committee shall comprise two physicians designated on behalf of the claimant physician by the President of the Medical Society, two physicians designated on behalf of the carrier by the Rating Board and one physician designated by the Commissioner. The carrier may name arbitrators of its own selection in any particular case, the nominations to be made through the Rating Board. The arbitrators designated by the Rating Board and the Commissioner shall be members of the Medical Society of the State of New York.

4. Notices relating to arbitration hearing. The Rating Board shall mail notice of the hearing containing the time and place thereof, with the names of the arbitrators which it has selected, at least eight days before the date of the hearing, to the carrier and the arbitrators selected by the Rating Board. The Medical Society shall mail like notice of the hearing together with the names of the arbitrators to the carrier.

Similar notice shall be sent to the arbitrator designated by the Commissioner.

5. Submission of formal agreements to arbitration required. The parties to arbitration shall sign a formal agreement, known as a "Submission," to submit the controversy to arbitration. The carrier shall show in the proper spaces on the Submission form the names of the parties, the sum in dispute

knowledge, and a copy of the notice of objection to medical bill for further action in arbitration.

6. Record of arbitration proceedings. The arbitrators shall be required to take the oath of office. The Rating Board shall appoint a recording clerk, qualified as a notary, who shall administer the oath and make a record of the proceedings on the pre-transcript of the

The claimant physician shall be required to pay a minimum arbitration fee which shall be subject to return as provided in Rule 9 of these rules. The claimant physician shall present his case, call his witnesses, present his proofs, and submit to questions

tive session, the arbitrators to be the only persons present at such session.

8. Forwarding arbitrators' decision or award. The decision or award shall be signed and acknowledged by the arbitrators. The original shall be mailed to the Labor Department and copies thereof shall be sent to the claimant physician, carrier, Medical Society, and Rating Board by the recording clerk.

9. Payment of award and arbitration fees. The award shall provide for payment as follows: The carrier shall draw two checks; one check for 95 per cent of the award payable to the order of the claimant physician, and the second check for 10 per cent of the award payable to the order of the Commissioner, the latter check to cover the carrier's share and claimant physician's share of the arbitration fee, provided, however, that if the carrier and claimant physician are each required to pay the minimum arbitration fee of \$2 00, the check to the claimant physician shall be for an amount equal to the award less \$2 00, the check to the Commissioner shall be for the sum of \$4 00, and the recording clerk shall return to the claimant physician the minimum arbitration fee of \$2 00 which was deposited by such physician at the time of the arbitration hearing. In the case where the claim is disallowed or where the award is for an amount less than \$2 00, the carrier shall mail its check for the minimum fee of \$2 00 to the Commissioner and the recording clerk shall

#### ARTICLE 1-A

##### Silicosis, and Other Dust Diseases

[This Article 4-A inserted by L. 1936, ch. 887, effective June 6, 1936]

and other dust diseases declared to be the policy in enacting this article,

2. The board of standards and appeals is hereby required to add to the industrial code, as provided in §§28 and 29 of the labor law, effective

dust hazard is present, of approved devices designed

the carrier. Such carrier shall then forward to the Rating Board the completely executed Submission together with a copy thereof excluding the

to eliminate such harmful dusts and to promulgate such other regulations as will effectively control the incidence of silicosis and similar diseases. [As amended by L. 1938, ch. 657.]

<sup>1</sup> Words "industrial commissioner and the industrial" stricken out by L. 1938, ch. 657.

<sup>2</sup> Words "of standards and appeals" inserted by L. 1938, ch. 657.

<sup>3</sup> Word "is" substituted for word "are" by L. 1938, ch. 657.

§66. Compensation payable for disability or death. Compensation shall not be payable for partial disability due to silicosis or other dust disease. In the event of temporary or permanent total disability or death from silicosis or other dust disease, notwithstanding any other provision of this chapter, compensation shall be payable under this article to employees in the employments enumerated in §3 of this chapter or to their dependents in the following manner and amounts: If disablement or death occur during <sup>1</sup>June, nineteen hundred thirty-six, not exceeding the sum of five hundred dollars; <sup>2</sup>thereafter the total of compensation and benefits payable for disability and death shall increase at the rate of fifty dollars each calendar month <sup>3</sup>until and including the month of December, nineteen hundred forty-three. The aggregate amount payable shall be determined by the total amount payable in the month in which disablement or death occurs. In no event shall such compensation exceed an aggregate total of <sup>4</sup>five thousand dollars <sup>5</sup>for temporary total disability and six thousand five hundred dollars for permanent total disability or death.

Compensation payable hereunder shall be paid from the eighth day following total disablement at the rate of sixty-six and two-thirds per centum of the average weekly wage to be computed under §14 of this chapter; but in no case shall compensation exceed twenty-five dollars per week nor in the event of total disability be less than eight dollars per week; provided, however, that in the event of death from such disease his dependents shall receive, in the manner provided by §§16 and 17 of this chapter, any balance remaining between the amounts paid for disability and the total compensation payable under this article.

Notwithstanding the provisions of §28 of this chapter, all claims for compensation resulting from inhalation of harmful dust, where the last exposure occurred between <sup>6</sup>September first, nineteen hundred thirty-five, <sup>7</sup>and June sixth, nineteen hundred thirty-six, shall be barred unless filed within one hundred and eighty days from <sup>8</sup>June sixth, nineteen hundred thirty-six. Liability in damages for disability or death due to any disease described in article 4-a of this chapter, in any case in which there was injurious exposure to the hazards of the disease prior to, and any exposure to such hazards subsequent to, September first, nineteen hundred thirty-five, shall be forever barred unless action therefor be begun within ninety days from the effective date of this act. <sup>9</sup>In addition to compensation herein provided, reasonable funeral expenses shall be paid as provided by Subdivision 1 of §16. [As amended by L. 1937, ch. 271; L. 1940, ch. 548; L. 1944, ch. 460.]

<sup>1</sup> Words "June, nineteen hundred and thirty-six" substituted for words "the first calendar month in which this act becomes effective" by L. 1940, ch. 548.

<sup>2</sup> Words "if disablement or death occur during the second calendar month after which this act becomes effective not exceeding the sum of five hundred and fifty dollars" stricken out by L. 1940, ch. 548.

<sup>3</sup> Words "until and . . . forty-three" inserted by L. 1940, ch. 548.

<sup>4</sup> Word "five" substituted for word "three" by L. 1940, ch. 548.

<sup>5</sup> Words "the effective date of this act and" stricken out by L. 1940, ch. 548.

<sup>6</sup> Words "and June sixth, nineteen hundred thirty-six" inserted by L. 1940, ch. 548.

<sup>7</sup> Words "June sixth . . . effective date of this act" inserted by L. 1940, ch. 548.

<sup>8</sup> Concluding sentence added by L. 1937, ch. 271.

<sup>9</sup> Words "for temporary . . . or death" inserted and sentence "The requirement as to payments into the special funds provided for in subdivisions eight and nine of section fifteen for each case of injury causing death in which there are no persons entitled to compensation shall not apply to any claim arising under this article" stricken out, by L. 1944, ch. 460.

§67. Liability of employer. An employer shall be liable for the payments prescribed by this article for silicosis or other dust disease when disability of an employee resulting in loss of earnings shall be due to an employment in a hazardous occupation in which he was employed, and such disability results within one year after the last injurious exposure in such employment; or, in case of death resulting from such exposure, if such death occurs within five years following continuous disability from such disease. The provisions of §44 of this chapter shall not apply to claims arising under this article.

The employer in whose employment the employee was last injuriously exposed in a hazardous occupation and the insurance carrier, if any, which was on the risk at the time of the last injurious exposure in such employment, shall be liable for any payments required by this article; the notice of injury and claim shall be made to such employer.

<sup>1</sup>Any exposure to the hazards of harmful dust in this state for a period of sixty days after September first, nineteen hundred thirty-five, shall be presumed, in the absence of substantial evidence to the contrary, to be an injurious exposure. [As amended by L. 1940, ch. 548.]

<sup>1</sup> This paragraph added by L. 1940, ch. 548.

§68. Medical treatment and <sup>1</sup>hospital care. Notwithstanding any other provisions of this chapter the medical treatment herein provided for <sup>2</sup>or, in lieu thereof, such hospitalization as the board may allow, shall be limited in the case of an employee disabled by an occupational disease due to or resulting from the inhalation of harmful dust to a period of ninety days <sup>3</sup>from the date of such disablement, but the requirement for such medical treatment <sup>4</sup>or hospitalization may be extended for an additional period, <sup>5</sup>not necessarily continuous, not to exceed <sup>6</sup>three hundred and sixty days upon the order of the industrial board.

<sup>7</sup>In determining the medical treatment, hospitalization, and other care required beyond the period of ninety days from the date of disablement, the board shall consider the recommendations contained in the report submitted by the committee of expert consultants as required under the provisions of section seventy-one of this chapter.

Copies of the order of the board directing the claimant as to the proper type of treatment, hospitalization, and other care to be secured shall be sent to all parties in interest and also to the attending physician and medical director of any hospital, sanatorium, or other place in which the treatment or care is being given. No claim for such treatment or care not in accordance with the requirements of the order of the board shall be valid and enforceable for any period more than five days after such notice of direction and report shall have been sent. [As amended by L. 1939, ch. 676; L. 1940, ch. 548.]

\* Word "hospital" inserted by L. 1939, ch. 676

\* Words "or, in lieu . . . may allow" inserted by L. 1939,

erted by L. 1939,

L. 1939, ch. 670.

erted by L. 1939,

ch. 678.

\* Words "three hundred and sixty" substituted for words "one hundred and eighty" by L. 1940, ch. 548, words "one hundred and eighty" had been substituted for word "ninety" by L. 1939, ch. 676.

\* Remainder of this section added by L. 1940, ch. 548

§69 Workers, when not entitled. If an employee, at the time of his employment, falsely represented in writing that he has not previously been disabled from the disease which is the cause of disability or death or has not received compensation or benefits under this article, no compensation shall be payable

§70 Special medical examiners. The industrial commissioner shall divide the state into five districts and in each district may appoint two or more special medical examiners who shall be licensed physicians in good professional standing, each of whom shall have had, at the time of his appointment, and immediately prior thereto, at least five years of practice in the diagnosis, care, and treatment of pulmonary diseases. Such examiners shall be employed on a per diem basis as the exigencies of the work may require. Fees of examiners shall be fixed by the industrial commissioner within the limits of the appropriation therefor. Each position of special medical examiner provided herein shall be in the exempt class of civil service.

Whenever a claim is made under this article and an examination of the claimant by an impartial physician is desired by any party in interest, the industrial commissioner shall order such medical examiners to make the necessary medical and x-ray examination of the claimant in an effort to obtain the medical facts in an impartial manner.

For the purposes of adjudication under this chapter, the industrial board shall adopt rules of practice and procedure and shall prescribe methods and standards under which physical examinations, x-rays, and other studies shall be conducted.

§71. Expert consultants. The industrial commissioner shall appoint as a committee of expert consultants on dust diseases three licensed physicians in good professional standing, each of whom shall have had, at the time of his appointment, and immediately prior thereto, at least ten years of practice in the diagnosis, care, and treatment of diseases of the pulmonary tract, along with interpretation of x-ray films thereof. One of such consultants shall be the commissioner. The commissioner shall be paid a salary of \_\_\_\_\_ dollars per year. \_\_\_\_\_ shall be in the \_\_\_\_\_

\_\_\_\_\_ filing of a claim for compensation hereunder, or notice thereof, the commissioner shall direct an examination of the claimant by the committee of expert consultants, or one of them, including such x-ray and other pathological examinations and tests as in their opinion may be \_\_\_\_\_ diagnosis \_\_\_\_\_ employment, and \_\_\_\_\_ treatment, hospitalization, and other care required. In \_\_\_\_\_ and report of \_\_\_\_\_ expert consultants \_\_\_\_\_ and report of the \_\_\_\_\_

committee. In the event that the claim is controverted upon any medical ground, the report shall be made by the full committee after a physical examination by at least one such expert consultant. The findings and opinions of a majority of the committee of expert consultants shall constitute the findings and opinion of the committee. The contents of such report of the committee of expert consultants introduced in evidence shall constitute prima facie evidence of fact as to the matter contained therein, and any of the makers of such report shall be subject to examination upon demand.

Copies of the report shall be sent to all parties in interest and also to the attending physician and medical director of any hospital, sanatorium, or

physician or medical director of any hospital or sanatorium or other place in which treatment or care provided for by this section is being given, to attend at such time or place as may be reasonably convenient, to consult with such expert consultants, or any of them, and to describe the nature and type of care or treatment being rendered, and for such attendance shall be entitled to receive a fee from the employer, or carrier, in an amount to be fixed by the commissioner in addition to any fee payable under §120.

In the event of a claim for death benefits, the committee of expert consultants upon their own initiative or upon the order of the commissioner or the board shall examine all available evidence pertaining to such claim, including medical and hospital records, x-rays and other reports made during the lifetime of the deceased, including the findings of any autopsy, and shall render its findings and report thereon.

The industrial commissioner or the industrial board shall on their own volition or on the application of either an employee, an employer, or an insurance carrier, direct such expert consultants to make examinations of claimants, to review the findings of special medical examiners, to read and review the files of compensation cases when necessary, and to inform the industrial commissioner and the industrial board of their opinion as to their findings in such cases. [As amended by L. 1940, ch. 548.]

\* Such committee of expert consultants shall as soon as practicable and at the direction of the indus-

tion for partial disability and other full benefits under this chapter in such cases. [As amended by L. 1940, ch. 548, L. 1944, ch. 460.]

\* Words "a committee of" inserted by L. 1940, ch. 548

\* Following sentence inserted by L. 1940, ch. 548.

\* Word "each" inserted by L. 1940, ch. 548

\* Word "at" eliminated by L. 1940, ch. 548

\* Words "to be fixed by the industrial commissioner not to exceed" stricken out and word "of" inserted by L. 1940, ch. 548.

\* Following four paragraphs inserted by L. 1940, ch. 548.

\* Final paragraph added by L. 1944, ch. 460

§72 Alternative remedy. The liability of an employer prescribed by this article shall be exclusive and in place of any other liability whatsoever, at common law or otherwise, to such employee, his personal representatives, husband, parents, de-

pendents, or next of kin, or anyone otherwise entitled to recover damages, at common law, or otherwise on account of any injury, disability, or death, caused by the inhalation of harmful dust, except that if an employer fail to secure the payment of compensation for his injured employees and their dependents as provided in §50 of this chapter, an injured employee, or his legal representative in case death results from the injury or disease, may, at his option, elect to claim compensation under this chapter, or to maintain an action in the courts for damages on account of such injury or disease; and in such an action it shall not be necessary to plead or prove freedom from contributory negligence nor may the defendant plead as a defense that the injury or disease was caused by the negligence of a fellow servant or that the employee assumed the risk of his employment, nor that the injury or disease was due to the contributory negligence of the employee.

*Re exclusiveness of remedy, see Del Busto v. Dupont de Nemours & Co., 167 Misc. 920; 259 App. Div. 1070; 204 S.B. 543.*

### EDUCATION LAW

§1264. Revocation of certificates; annulment of registrations . . . . .

2. The license or registration of a practitioner of medicine may be revoked, suspended, or annulled or such practitioner reprimanded or disciplined in accordance with the provisions and procedure of this article upon decision after due hearing in any of the following cases: . . . . .

(f) That a physician has directly or indirectly requested, received, or participated in the division, transference, assignment, rebate, splitting, or refunding of a fee for, or has directly or indirectly requested, received, or profited by means of a credit or other valuable consideration as a commission,

discount, or gratuity in connection with the furnishing of medical, surgical, or dental care, diagnosis or treatment or service, including x-ray examination and treatment, or for or in connection with the sale, rental, supplying, or furnishing of clinical laboratory services or supplies, x-ray laboratory services or supplies, inhalation therapy service or equipment, ambulance service, hospital or medical supplies, physiotherapy or other therapeutic service or equipment, artificial limbs, teeth, or eyes, orthopaedic or surgical appliances or supplies, optical appliances, supplies or equipment, devices for aid of hearing, drugs, medication, or medical supplies, or any other goods, services, or supplies prescribed for medical diagnosis, care, or treatment under this chapter, except payment, not to exceed thirty-three and one-third per centum of any fee received for x-ray examination, diagnosis, or treatment, to any hospital furnishing facilities for such examination, diagnosis, or treatment. [This Paragraph (f) added by L. 1944, ch. 466.]

For effect of fee splitting, etc., on authorization of physicians to treat injured workmen under the Workmen's Compensation Law, see §13-d, Subdivision 2, of such Law.

### INSURANCE LAW

§40. Insurer's license required; issuance, revocation of license . . . . .

8. The superintendent may impose a penalty of not to exceed twenty-five hundred dollars upon any insurer required to be licensed under the provisions of this chapter, if, after notice to and a hearing of such insurer, he shall find that such insurer has unreasonably failed to comply with requirements imposed by the workmen's compensation law. The action of the superintendent shall be subject to judicial review. [This Paragraph 8 added by L. 1944, ch. 470.]

*It is suggested that physicians interested in Workmen's Compensation cut out and bind pages 2724-2740 for future reference.*

### NURSE SHORTAGE IN SERVICES IS CRITICAL

As a result of a critical shortage of nurses in the U.S. Army, the War Manpower Commission Procurement and Assignment Service has sent telegrams to all state procurement and assignment committees requesting that additional names of nurses be made available to the American Red Cross for recruitment purposes, Paul V. McNutt, WMC Chairman, announced on November 22.

Stating that he had been informed that 10,000 nurses must be recruited for the Army immediately in order to care adequately for wounded and sick soldiers overseas and at home, Mr. McNutt said the committees have been asked to cooperate with Nursing Councils for War Service in meetings of nurses in twenty-five of the country's larger cities, at which the seriousness of the Army's nursing needs will be explained.

Mr. McNutt said that he had been informed by Maj. Gen. Norman T. Kirk, Surgeon General of the Army, that the Army's need for more nurses has been heightened by the activation during November of hospitals it had not been expected to

organize before next March. This is because, he was informed, of the activity on all war fronts and the ever increasing number of battle casualties.

The Veterans Administration, Mr. McNutt said, is also experiencing a serious need for additional nurses. About 1,000 additional nurses are urgently required to care for the growing number of servicemen in Veterans Administration hospitals.

The Navy, Mr. McNutt said, will continue to need about 500 nurses a month for several more months.

"Our nurses who have already responded to the needs of the services are doing a splendid job, but many more than are at present enrolled are needed. I would like to see every nurse who has been declared available for military service respond to this call. I would also like to see every young nurse now graduating who can do so offer her services."

WMC pointed out that nurses who enter the services are commissioned, and at the end of the service will enjoy all rights extended to the armed forces under the G. I. Bill of Rights.

# Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York are published in this section of the JOURNAL. The members of the committee are Oliver W. H. Mitchell, M.D., Chairman (423 Greenwood Place, Syracuse); George Bucher, M.D., and Charles D. Post, M.D.

## Saranac Lake Medical Society Has Two Postgraduate Sessions

THE Saranac Lake Medical Society met on December 6, 1944, at 8:00 P.M. in the John Black Room of the Saranac Laboratory, Saranac Lake, for a lecture entitled "Distases of the Biliary Tract," by Dr. Julian Rose, instructor in medicine at Long Island College of Medicine.

On December 20, 8:00 P.M., the society met again in the John Black Room of Saranac Labora-

... medicine  
... Columbia  
... and Treat-

... cooperative  
... endeavor between the Medical Society of the State of New York and the New York State Department of Health

## "Penicillin Therapy"

THE medical staff of Veterans' Memorial Hospital, Ellenville, met on December 5 at 9:00 P.M. at the Wayside Inn in Ellenville, for postgraduate instruction. A lecture, "Penicillin Therapy," was delivered by Dr. R. C. Arnold, Surgeon, U.S. Public Health Service, Venereal Disease Re-

search Laboratory, U.S. Marine Hospital, Staten Island.

This instruction was provided by the Medical Society of the State of New York with the cooperation of the New York State Department of Health

## Jaundice

POSTGRADUATE instruction in general medicine was given to the Jefferson County Medical Society on December 14 at 6:30 P.M. at the Black

River Valley Club, Watertown. Dr. William F. Lipp, assistant in medicine, University of Buffalo School of Medicine, spoke on "The Treatment of Jaundice"

## MANHATTAN HOSPITALS SET \$12,000,000 AS WAR LOAN GOAL

Manhattan's thirty-three voluntary hospitals have set a Sixth War Loan quota of \$12,000,000, with the majority of hospitals sighting their bond sales at the purchase of fleets of field ambulances and ambulance planes, it has been reported by John McCormack and Mrs. Donald B. Woodward, co-chairmen, hospital division of the War Finance Committee for New York.

of the faculty of the New York Medical College are joining in the selling with bond talks to the Army and Navy doctors who are their students.

Many of the voluntary hospitals' war bond committees are headed by women, a large number of whom are wives of attending physicians. Among these women is Mrs. Charles B. Halsey at Post Graduate Hospital, now a first lieutenant in the Blue Star Brigade. Post-Graduate's bond quota is \$413,000, the cost of a BPM Mariner Patrol Bomber, a naval hospital plane.

Other hospitals which have selected "mercy" goals for the Sixth War Loan are: St. Luke's, \$250,000, for two ambulance planes, Jewish Memorial, \$413,000, for a BPM Mariner Patrol Bomber; Hospital for Joint Diseases, \$125,000, for an ambulance plane, St. Vincent's, \$125,000, for an ambulance plane, N.Y. Orthopaedic, \$125,000, for an ambulance plane; St. Elizabeth's, \$125,000, for an ambulance plane, Memorial Hospital, \$125,000, for an ambulance plane; Downtown, \$125,000, for an ambulance plane, Knickerbocker, \$18,750, for a fleet of twenty-five field ambulances; French, \$18,750, for a fleet of twenty-five field ambulances, Manhattan Eye, Ear and Throat, \$68,250, for thirty-five field ambulances.

The nurses of Beth Israel Hospital are particularly active in the Blue Star Brigade, and already have in their ranks three lieutenant colonels, one major, and three captains, who have helped sell the start of the marked for pur-

## A.M.A. Meeting Transferred to Philadelphia

THE Ninety-Fifth Annual Session of the American Medical Association will be held in Philadelphia June 18 to 22, 1945. This session was originally scheduled to be held in New York June 11 to 15, but because of untoward conditions growing out of the war emergency it was found that needed facilities would not be available in that city.

A very cordial invitation has been extended to the Association by the Philadelphia County Medical Society to hold the 1945 session in that city. The Philadelphia Convention and Tourists Bureau, the Hotel Association, those concerned with the operation of transportation facilities and other civic groups have given assurances that everything possible will be done to contribute to the success of a meeting in Philadelphia. Final arrangements are being made as rapidly as possible.

Hotel reservations will be made through a central office in Philadelphia. It is highly desirable that reservations be made as early as possible. Those who expect to attend the Philadelphia session are

urgently requested to refrain from making reservations in more than one hotel. In numerous instances at the annual session held in Chicago in 1944, and at other sessions previously held, individual physicians have made reservations at two or three hotels and on arrival at the place of meeting have completed their reservations at one hotel and failed to cancel other reservations. The result has been that many physicians have found it impossible to secure accommodations. If this practice is persisted in it will become increasingly difficult for the Association to find a satisfactory place of meeting.

At the Chicago session several hotels had a large number of reservations which they had made in good faith only to find that multiple reservations made by individuals, which were not needed, were not canceled, and the result was that the hotels had vacant accommodations, which after a short time were given over to persons who were not concerned with the annual session of the American Medical Association.—J.A.M.A., Nov. 25, 1944

## Baruch Committee Makes New Grants for Physical Medicine

THE Administrative Board of the Baruch Committee on Physical Medicine has announced the granting of an additional total sum of \$185,000, which is being given by Mr. Bernard M. Baruch for the advancement of the program in physical medicine and the rehabilitation of the war-disabled.

This sum has been divided into seven grants, as follows: \$50,000 to the Massachusetts Institute of Technology, Cambridge, Massachusetts; \$40,000 to the Medical School of the University of Minnesota, Minneapolis; \$30,000 to the Medical School of Harvard University, Boston; \$30,000 to the Medical School of the University of Southern California, Los Angeles; \$15,000 to the Medical School of the University of Iowa, Iowa City; \$15,000 to the Medical School of the University of Illinois, Chicago; \$5,000 to Marquette University Medical School, Milwaukee, Wisconsin.

The grants to the Massachusetts Institute of Technology and the University of Minnesota are in addition to the gift of \$1,100,000 made by Mr. Baruch in April, 1944, at which time grants were made to Columbia University's College of Physicians and Surgeons, New York University College of Medicine, the Medical College of Virginia, and for minor research and fellowship programs for the advancement of physical medicine.

The present grant to the Massachusetts Institute of Technology is in support of a five-year program of training and research in electronics, instrumentation, and physics in relation to medicine, to be carried on under the auspices of the Department of Biology and Biological Engineering. Dr. Frank H. Krusen, director of the Baruch Committee, said that Mr. Baruch is particularly interested in the field of electronics as applied to medicine.

## Pay Allowances for Women Medical Officers

LEGISLATION under which women officers of the Army Medical Corps will be entitled to receive the same pay allowances for their dependents as are paid to all other commissioned personnel of the Army became effective on October 1.

An act authorizing the commissioning of women physicians in the Medical Corps was approved in April, 1943, and provided that they should "receive the same pay and allowances and be entitled to the same rights, privileges, and benefits as members of the Officers Reserve Corps of the Army." The

Comptroller General subsequently ruled that they were not entitled to allowances for dependents.

The new law, designed to meet the Comptroller General's objections, is not retroactive to the date of women officers' commissions. The dependents for whom allowances may be paid are "husband, a child or children, or a parent or parents in fact dependent" upon the officer "for their chief support."

Approximately seventy-five women have been commissioned to date in the Medical Corps.—Release, Office of the Surgeon General, Nov. 16, 1944

## General Simmons Honored by American Society of Tropical Medicine

AT THE annual meeting of the American Society of Tropical Medicine in St. Louis, Brig. Gen. James S. Simmons, USA, Chief of the Preventive Medicine Service, was presented (November 15) with the Walter Reed Medal. This medal, "cast

in bronze," was established by the Society in 1934, to be awarded periodically to an individual or an institution in recognition of meritorious achievement in tropical medicine.—Release from the Office of the Surgeon General, Nov. 16, 1944

## Major Lyons Receives Legion of Merit for Penicillin Research

MAJOR Champ Lyons, MC, of West Newton,

and limbs of soldiers have been saved, and the dis-

perience in practical surgery, has cast new light on the age-old problem of wound surgery. At no time has he spared himself mentally or physically, and the example he has set is an inspiration to all surgeons in the service "

## County News

### Albany County

Dr. Clay, and Treatment of the College of Pharmacy, of the paper was opened by Drs John W. Ghormley, Thomas J. O'Donnell, and F. W. Dodge.

Dr. Murray is associate professor of surgery, College of Physicians and Surgeons, Columbia University, and associate attending surgeon, Presbyterian Hospital, New York City.

A meeting of the Eastern New York Eye, Ear, Nose, and Throat Society was held in the University Club in Albany on November 2

Dr. Edward J. Whalen, Hartford, Connecticut, spoke on the use of sulfa drugs in the treatment of nasal sinus disease.

The general topic of sinus disease was reviewed by Dr. John J. Ranney, who acted as discussion master. Dr. Daniel Cuning, New York specialist and formerly of Albany, discussed the topic from the medical viewpoint, and Dr. Crawford R. Green, Troy, spoke from the view point of the general practitioner.\*

In an address before members of the American Legion Auxiliary in Albany on November 16, Dr. Robert E. Plunkett, general superintendent of tuberculosis hospitals of the State Health Department, urged the establishment of free tuberculosis treatment in New York State hospitals \*

### Erie County

A Kenmore attorney, Joseph J. Guariglia, will aid the Medical Society of the County of Erie in enforcing the medical provisions of the Workmen's Compensation Law, a duty with which the society is charged by law. The appointment of Mr. Guariglia as secretary to the society's compensation board was voted unanimously by the committee of the society.\*

Greater N

body which shall be able to represent officially the organized medical profession of the entire city in matters of city-wide interest.

\* Asterisk indicates that item is from a local newspaper

Discussion of this proposal appeared in the November 18 issue of *Journal of the Medical Society of the County of New York*.

### Greene County

At the annual meeting of the Medical Society of the County of Greene held on October 26 the following officers were elected:

president, Dr. L. G. Mulbury; vice-president, Dr. Frances P. Wiese; secretary, Dr. W. M. Rapp; treasurer, Dr. M. H. Atkinson; and delegate to the State Society, Dr. K. F. Bott.

### Kings County

A stated meeting of the county society was held in MacNaughton Auditorium on November 21 at 8:45 P. M.

A special feature of the program was the presentation to the society of a portrait of the late Dr. Henry Joachim. Dr. Milton G. Wasch made the presentation and the gift was accepted by Dr. Merrill N. Foote on behalf of the society.

Two papers on proctology were read—"The Present Status of Caudal Anesthesia in Proctology," by Dr. Louis Hirschman, professor of proctology at Wayne Michigan in Recta ! professor of Medicine, Brooklyn

Dr. Frederick E. Elliott spoke on "United Medical Service, Inc."

The nominating committee announced the candidates for office for 1945.

His Holiness, Pope Pius XII, has conferred upon two physicians of the Diocese of Brooklyn the Papal Honor of Knight of St. Gregory the Great. They are Drs. Thomas M. Brennan and Thomas A. McGoldrick.

Dr. Brennan, a native of Brooklyn, is chairman of the Board of Trustees and of the Publication Committee of the Medical Society of the State of New York, as well as a member of the Council of that of the staff of St. the medical board

of Brooklyn, is a past president of the State Medical Society and a former chief surgeon of the City Police Department. For over forty years he has served on the staff of St. Peter's Hospital, Brooklyn. He is director of

medicine at St. Anthony's Hospital, Woodhaven, and Welfare Hospital, Welfare Island.

. . .

The forty-seventh annual meeting of the Associated Physicians of Long Island will be held at St. John's Hospital, Brooklyn, on Saturday, January 27, 1945.

The morning program will consist of clinics. The scientific session, at 2:30 P.M., will consist of six ten-minute papers with discussions on diversified subjects. The annual dinner will take place at 6:30 P.M. at the Brooklyn Club.

. . .

Mr. Charles Frankenburger, librarian for the county society, gave his annual course of lectures on medical literature and bibliography to the first-year class of the Long Island College of Medicine from November 10 through December 8. The lectures were illustrated with lantern slides. Members of the county society were invited to attend.

. . .

Dr. Jean A. Curran, president of the Long Island College of Medicine, outlined a proposed plan for expansion of the college's plant and research facilities at a dinner which launched the fall program of the College's second annual Development Fund.

He said that the expansion will be made possible through the fund drive, in which \$100,000 is sought. Dr. Nathaniel P. Rathbun, chairman of the Fund, presided at the dinner, which was attended by more than seventy-five parents of second-year students.

Dr. William Dock, professor of medicine, explained that communities which have hospitals connected with medical schools are the first to obtain new therapeutic agents for the care of diseases.

Appeals to industry in Brooklyn will be made by the Business Interests Division, and the Women's Division will canvass the organized women's club during the fall and winter. Parents' groups started their activities last spring with meetings in all five boroughs.\*

#### Lewis County

Officers and committees of the county society for the year 1945 are: president, Dr. Harry E. Chapin, Lowville; vice-president, Dr. Bruce M. Phelps, Lowville; secretary-treasurer, Dr. Joseph F. Rudmin, Port Leyden; delegate to the State Society, Dr. Edgar O. Boggs, Lowville; alternate delegate, Dr. Thomas A. Lynch, Lowville; censors: Dr. David J. O'Connor, Croghan, Dr. Phelps, Dr. Chapin; committee on legislation: Dr. Lynch, *chairman*, Dr. Boggs, Dr. Reginald D. Gerrard, Lowville; committee on public health and education: Dr. Phelps, *chairman*, Dr. Rudmin, Dr. Gregori O. Volovic, Lowville; subcommittee on industrial health: Dr. Boggs, Dr. O'Connor; committee on school health: Dr. Lynch, Dr. Paul H. von Zierolshofen, Croghan; committee on tuberculosis: Dr. Volovic, Dr. H. J. Stenger, Lyons Falls; committee on workmen's compensation: Dr. Chapin, *chairman*, Dr. Rudmin, Dr. Boggs; committee on grievance (workmen's compensation): Dr. Chapin and Dr. Boggs.

#### Monroe County

Dr. Edward G. Whipple, Rochester, has been named one of three special consultants to the State

Department of Labor on dust diseases, especially silicosis.

The commission was established by the State Legislature several years ago after an outbreak of silicosis in industry.

Dr. Whipple came to Rochester in 1911 as executive secretary and medical director of the Rochester Public Health Association. He served in that capacity until 1916, when he began to practice general medicine. In World War I he was a captain in the Medical Corps.

He has served on the staffs of Strong Memorial Hospital, where he is a consultant in medicine, Genesee, Highland, and Rochester General, and is a consultant in medicine at the County Hospital.\*

#### Nassau County

At the regular monthly meeting of the county society, held on November 28 at 9:00 P.M. in Mercy Hospital Auditorium, Dr. Alexander O. Gettler, professor of chemistry and toxicology at New York University, toxicologist to the Chief Medical Examiner's Office, New York City, and consulting toxicologist to the Department of Hospitals, New York City, spoke on "Toxicological Problems in a General Hospital."

. . .

Dr. William H. Ross, of Brentwood, discussed the hazards of socialized medicine at a meeting of the Bay Shore Library Club on November 6.

#### New York County

Prejudice against women doctors is rapidly diminishing, but if it is to disappear altogether "all women in medicine must now regard themselves as doctors, not as women doctors, and must have the courage to accept equality," Dr. Donal Sheehan, acting Dean of the New York University College of Medicine, declared on November 14 at a dinner of the Women's Medical Association of New York City. One hundred doctors, students, and professors of medical colleges attended the meeting, which was held at the Cosmopolitan Club.

Dr. Joseph Hinsey, Dean of Cornell University Medical College, Dr. Jean Curran, president and Dean of Long Island College of Medicine, Miss C. Mildred Thompson, Dean of Vassar College, and Miss Charlotte Anne Keefe of the Dalton School participated in a forum discussion on the future of medical education and the part women will play in medicine after the war.\*

. . .

Dr. Henry E. Meloney, professor of preventive medicine, New York University College of Medicine, has been appointed representative from the American Society of Tropical Medicine to the division of medical sciences of the National Research Council.

. . .

In his annual report to Nicholas Murray Butler, President of Columbia University, Dr. Willard C. Rappleye, Dean of the College of Physicians and Surgeons, calls attention to new demands which he foresees will be placed upon medicine as a result of the war. War casualties will be such as to require immediate planning for better training and development of special skills in all fields of medicine, Dr. Rappleye believes.

"It is generally agreed that tropical diseases constitute one of the major problems of the war," Dr.

Rappleye stated. "The widespread incidence of these disorders among the armed forces and the probability of their increasing among civilians after the war through commercial contacts, shipping, and travel, are fully recognized." Dr. Rappleye also called attention to the new methods now being developed for the care of arthritis and other joint diseases.

Dr. Joseph D. Kelly, of the Manhattan Eye, Ear, and Throat Hospital, has been appointed professor and chairman of the ophthalmology at the New York City School of Medicine, Washington, D. C., in 1942.

A new pamphlet on "Child Care and Development" has been issued by the Community Service Society of New York. It sets up for each age, beginning at birth and carrying on to 5 years, certain developmental signs for the child, such as height, weight, diet, sleep, physical development, and recommended practices. The pamphlet is one of the most useful documents that a physician can make available to a nurse or to members of the family. As a public service the pamphlet is sold at 10 cents plus postage on orders for one to one hundred, and 8 cents plus postage on orders over one hundred.

On October 12 a dinner was given at the Waldorf-Astoria in honor of Dr. Abraham A. Brill, lecturer in psychoanalysis and psychosexuality, Columbia University, to celebrate his seventieth birthday. Dr. Louis Casamajor was toastmaster, and speakers were Dr. Leonard Woodburn, who had been raised amounting to about \$6,000, with which he intends to endow a library. It was also announced that a library in the new building of the New York Psychoanalytic Institute will be named in honor of Dr. Brill.

A memorial meeting was held at Columbia University by the Polish Institute of Arts and Sciences in America, October 20, to mark the tenth anniversary of the death of Marie Sklodowska Curie. Six departments of the university, including chemistry, chemical engineering, East European languages, medicine, physics, and radiology, participated. Among the speakers were W. A. Swietoslawski, E. E. Me, president of the who spoke on Kasimir Fajan, Arbor, a member of the Modern Development of Chemistry and Physics.

#### Oneida County

The November meeting of the Utica Academy of Medicine was held on November 16 at the Hotel Utica, with Dr. Ward J. MacNeal, director of laboratories at New York Post-Graduate Medical School,

as the main speaker. The title of Dr. MacNeal's address was "Blood Stream Infection and Endocarditis." Discussion was opened by Lt. Col. Howard P. Lewis, of Rhoads Hospital, Dr. Edwin P. Russell, and Dr. Robert W. Hurd.

Other features of the program were the "Overseas Mail Bag" and "The Campaign in Italy" by Lt. Col. Walter Pugh. The program was preceded by a dinner at 7:00 p. m.

Dr. Newton J. T. Bigelow, Deputy Commissioner, New York State Department of Mental Hygiene, addressed the Utica Council of Social Agencies on October 24. His topic was "The Child Guidance Clinic's Value to the Community."

#### Ontario County

Capt. John A. Crowther, of Honeyoye, who has just returned after twenty-one months in the South Pacific, gave an informal talk on November 3 at the monthly meeting of the Canandigua Medical Society in the home of Dr. Malcolm R. Blakeslee, Shortsville. He told of Army life in the tropics, of his varied experiences, and answered many questions.

Besides Dr. Crowther, guests were Dr. Frederick C. Robbins, Brigham Hall, and Dr. William C. Eakner, Chifton Springs. Dinner preceded the program.

#### Putnam County

Sandor Rado, M.D., clinical professor of psychiatry, College of Physicians and Surgeons, Columbia University, was the guest speaker at the . . . el, New York, . . . Dr. Rado's . . . from the Point

The officers for the year 1944-1945 are as follows: president, Dr. George H. Steacy, Lake Mahopac; vice-president, Dr. Frank C. Genovese, Patterson; and secretary-treasurer, Dr. Garrett W. Vink, Carmel.

#### Quecas County

##### Hills Inn

The presentation was made by Dr. L. Howard Moss, a member of the medical board and of the board of trustees of Jamaica Hospital, where Dr. Neal was . . . and . . .

was arranged by Dr. Neal's friends and colleagues at the hospital. Thomas D. Austin, trustee, was the toastmaster, and speakers included Clarence A. Ludlum, chairman of the board, Dr. Edward J. Buxbaum, Dr. A. A. de Poto, and Francis C. Leu-

which he

Among the guests was a delegation from the Medical Jurisprudence Association of New York, of which Dr. Neal is a member. Two physicians who were graduated with Dr. Neal in the class of 1905

medicine at St. Anthony's Hospital, Woodhaven, and Welfare Hospital, Welfare Island.

. . .

The forty-seventh annual meeting of the Associated Physicians of Long Island will be held at St. John's Hospital, Brooklyn, on Saturday, January 27, 1945.

The morning program will consist of clinics. The scientific session, at 2:30 p.m., will consist of six ten-minute papers with discussions on diversified subjects. The annual dinner will take place at 6:30 p.m. at the Brooklyn Club.

. . .

Mr. Charles Frankenburger, librarian for the county society, gave his annual course of lectures on medical literature and bibliography to the first-year class of the Long Island College of Medicine from November 10 through December 8. The lectures were illustrated with lantern slides. Members of the county society were invited to attend.

. . .

Dr. Jean A. Curran, president of the Long Island College of Medicine, outlined a proposed plan for expansion of the college's plant and research facilities at a dinner which launched the fall program of the College's second annual Development Fund.

He said that the expansion will be made possible through the fund drive, in which \$100,000 is sought. Dr. Nathaniel P. Rathbun, chairman of the Fund, presided at the dinner, which was attended by more than seventy-five parents of second-year students.

Dr. William Dock, professor of medicine, explained that communities which have hospitals connected with medical schools are the first to obtain new therapeutic agents for the care of diseases.

Appeals to industry in Brooklyn will be made by the Business Interests Division, and the Women's Division will canvass the organized women's club during the fall and winter. Parents' groups started their activities last spring with meetings in all five boroughs.\*

#### Lewis County

Officers and committees of the county society for the year 1945 are: president, Dr. Harry E. Chapin, Lowville; vice-president, Dr. Bruce M. Phelps, Lowville; secretary-treasurer, Dr. Joseph F. Rudmin, Port Leyden; delegate to the State Society, Dr. Edgar O. Boggs, Lowville; alternate delegate, Dr. Thomas A. Lynch, Lowville; censors: Dr. David J. O'Connor, Croghan, Dr. Phelps, Dr. Chapin; committee on legislation: Dr. Lynch, *chairman*, Dr. Boggs, Dr. Reginald D. Gerrard, Lowville; committee on public health and education: Dr. Phelps, *chairman*, Dr. Rudmin, Dr. Gregori O. Volovic, Lowville; subcommittee on industrial health: Dr. Boggs, Dr. O'Connor; committee on school health: Dr. Lynch, Dr. Paul H. von Zierolshofen, Croghan; committee on tuberculosis: Dr. Volovic, Dr. H. J. Stenger, Lyons Falls; committee on workmen's compensation: Dr. Chapin, *chairman*, Dr. Rudmin, Dr. Boggs; committee on grievance (workmen's compensation): Dr. Chapin and Dr. Boggs.

#### Monroe County

Dr. Edward G. Whipple, Rochester, has been named one of three special consultants to the State

Department of Labor on dust diseases, especially silicosis.

The commission was established by the State Legislature several years ago after an outbreak of silicosis in industry.

Dr. Whipple came to Rochester in 1911 as executive secretary and medical director of the Rochester Public Health Association. He served in that capacity until 1916, when he began to practice general medicine. In World War I he was a captain in the Medical Corps.

He has served on the staffs of Strong Memorial Hospital, where he is a consultant in medicine, Genesee, Highland, and Rochester General, and is a consultant in medicine at the County Hospital.\*

#### Nassau County

At the regular monthly meeting of the county society, held on November 28 at 9:00 p.m. in Mercy Hospital Auditorium, Dr. Alexander O. Gettler, professor of chemistry and toxicology at New York University, toxicologist to the Chief Medical Examiner's Office, New York City, and consulting toxicologist to the Department of Hospitals, New York City, spoke on "Toxicological Problems in a General Hospital."

. . .

Dr. William H. Ross, of Brentwood, discussed the hazards of socialized medicine at a meeting of the Bay Shore Library Club on November 6.

#### New York County

Prejudice against women doctors is rapidly diminishing, but if it is to disappear altogether "all women in medicine must now regard themselves as doctors, not as women doctors, and must have the courage to accept equality," Dr. Donal Sheehan, acting Dean of the New York University College of Medicine, declared on November 14 at a dinner of the Women's Medical Association of New York City. One hundred doctors, students, and professors of medical colleges attended the meeting, which was held at the Cosmopolitan Club.

Dr. Joseph Hinsey, Dean of Cornell University Medical College, Dr. Jean Curran, president and Dean of Long Island College of Medicine, Miss C. Mildred Thompson, Dean of Vassar College, and Miss Charlotte Anne Keefe of the Dalton School participated in a forum discussion on the future of medical education and the part women will play in medicine after the war.\*

. . .

Dr. Henry E. Meleney, professor of preventive medicine, New York University College of Medicine, has been appointed representative from the American Society of Tropical Medicine to the division of medical sciences of the National Research Council.

. . .

In his annual report to Nicholas Murray Butler, President of Columbia University, Dr. Willard C. Rappleye, Dean of the College of Physicians and Surgeons, calls attention to new demands which he foresees will be placed upon medicine as a result of the war. War casualties will be such as to require immediate planning for better training and development of special skills in all fields of medicine, Dr. Rappleye believes.

"It is generally agreed that tropical diseases constitute one of the major problems of the war," Dr.

## Reorganize Air Surgeon's Office

Gen. David N. W. Grant, the Air Surgeon, effective August 15.

Brig. Gen. Glenn succeeded Col. Walter S. Jensen, who has been assigned to an important post overseas.

Other new assignments include those of Col. Henry C. Chenault, executive officer, who has been named director of professional services, Col. Oliver K. Niess, base surgeon and commanding officer of the Regional State Hospital, Mitchel Field, New York, who has been named director of administration, and Col. Richard L. Meiling, who will act as special assistant to the Air Surgeon.

The reorganization places the Director of Ad-

ministration over the Operations, Personnel, and Supply Divisions, while the Director of Professional Services will supervise the Professional, Aviation Medicine, Convalescent Training, Research, and Statistics Division. Two divisions have received new designations. The Medical Services Division will be called the Professional Division, and the former Professional Division will be known as the Aviation Medicine Division.

The status of the division chiefs remains un-

Col. George L. Ball, Col. Howard A. Rusk, Col. George F. Baier, III, Operations Division; Col. E. L. Gann, Personnel Division; Col. William P. Holbrook, Professional Division; Col. Lloyd E. Griffin, Research Division; Col. Joseph Berkson, Statistics Division; Col. Gustave E. Ledford, Supply Division, and Maj. William H. Perkins, Office Services.—J.A.M.A., Sept. 16, 1944

### Competition for Prize Essays

The Merrit H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win a prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1945, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York 17, New York.

CHAS. GORDON HEYD, M.D., Chairman  
Committee on Prize Essays

# Woman's Auxiliary

To the Medical Society of the State of New York

## County News

**Broome County.** The Women's Auxiliary to the Broome County Medical Society met in the Nurses' Home, Ideal Hospital, Endicott, recently.

Mrs. Manuel M. Monserrate, president, presided at the business meeting. Mrs. Harold W. McNitt, chairman of the war-bond drive, outlined plans for her workers in the present campaign.

Mrs. Charles R. Seymour gave a report of the Fall meeting of the State Executive Board, held in Buffalo last month.

Congratulations were extended to Mrs. Goode R. Cheatham, a member, on being chosen as one of the outstanding women in the community in the recent awards presented by the women's clubs of the Triple Cities.

It was announced that on December 12 the county medical society will entertain auxiliary members at dinner in the Binghamton Club. Wives of doctors in service will be guests at that time.

Following the business meeting, the group played cards and refreshments were served on a table arranged with pink and white chrysanthemums flanked with white tapers in crystal holders.

Endicott members serving as hostesses were Mrs. John Kane, Mrs. R. D. Mead, Mrs. M. W. Welch, Mrs. J. A. Kalb, Mrs. F. G. Moore, Mrs. J. D. Tocco, Mrs. J. MacD. Mallory, Mrs. John Malia, and Mrs. Cheatham.

**Nassau County.** At the regular meeting of the Nassau County Auxiliary on October 31, in the Nassau Hospital Auditorium, Miss Mildred Montag, director of the School of Nursing at Adelphi College, and representative of the Nassau County Nurse Recruitment Committee, spoke on nurse recruitment; the second speaker was Lt. Marie Griggs, of the Naval Reserve Nurse Corps, who told of her experience during fourteen months of duty in the Aleutian Islands. The speakers were introduced by Mrs. Freeman Miller, of Freeport, the program chairman. Mrs. Louis A. Van Kleeck, of Manhasset, presided.

The November meeting of the county auxiliary was held on Tuesday evening, November 28, at 8:15 p.m., in the Nassau Hospital Auditorium. The speaker was Dr. Frederic E. Elliott, whose topic was "United Medical Service, Inc." This is the name of the voluntary medical expense insurance plan which

is endorsed by our local and state medical societies.

The December meeting was a Christmas party on December 12 at 8:30 p.m. Members brought toy for the foster children of Nassau County.

On December 9 there was a dinner dance with the county medical society at the Garden City Hotel at 8:30 p.m.

During the threatened poliomyelitis epidemic members of the Auxiliary volunteered to help in the keeping of records of cases brought to Meadowbrook Hospital. Under the leadership of Mrs. S. Alto Dallgaard, two members reported daily for morning or afternoon sessions. Some of the women who participated are: Mrs. Robert M. Bogue, Mrs. Arthur D. Jacques, Mrs. Ralph E. Perry, Mrs. Eugene J. Miele, Mrs. George S. Comstock, Mrs. G. Border Granger, Mrs. Henry Buel Smith, Mrs. Benjamin W. Seaman, Mrs. Eugene H. Coon, Mrs. John M. Quinn, Mrs. William G. Burke, Mrs. Arthur C. Martin, Mrs. Albert M. Bell, Mrs. Byron D. St. John, and Mrs. Louis A. Van Kleeck.

**Schenectady County.** The auxiliary to the Schenectady County Medical society met on October 2 at the Hotel Van Curler in Schenectady. Mrs. Arthur Congdon presided. Dr. Charles F. Rourke, president of the medical society, addressed the meeting. Mrs. Rebekah Hash Toller, of the Schenectady Public Library, reviewed several current books, including *The World of Washington Irving*, by Van Wyck Brooks, and suggested books for Christmas giving.

Those attending were Mrs. D. Howard Lester, Mrs. Thomas G. Adinolfi, Mrs. Funston J. Eckels, Mrs. J. H. Kalteux, Mrs. Joseph L. Cirincione, M. F. Leslie Sullivan, Mrs. N. H. Rust, Mrs. Fred C. Reed, Mrs. A. N. Crouch, Miss Katherine Warner, Mrs. Albert W. Greene, Mrs. James E. Smith, Mrs. W. F. MacDonald, Mrs. G. Marcellus Clowe, Mrs. A. H. Congdon, Mrs. William J. Jameson, Dr. Debora C. Hornby, Mrs. Edward B. O'Keefe, Mrs. Roland L. Faulkner, Mrs. Ralph J. Hotchkiss, Mrs. Donald Nitchman, Mrs. Walter J. Reinach, Mrs. A. A. Samorini, Mrs. Charles F. Rourke, Mrs. Gomer Richards, Mrs. James M. Blake, Mrs. Michael Slovak, and Mrs. Herman Galster.

## CHRISTMAS SEAL SALE UNDER WAY

Wartime prevention and control of tuberculosis and diphtheria show encouraging progress, according to a joint statement by Judge Peter Cantline, of Newburgh, and George J. Nelbach, of Yonkers, chairman and executive secretary of the Committee on Tuberculosis and Public Health of the State Charities Aid Association.

The Association, with its 62 county and city tuberculosis and health associations, is the sponsor for the 1944 Christmas Seal sale now under way to provide funds for cooperative public health activities in the State.

## HADASSAH AIDS TUBERCULOSIS FIGHT

At the thirtieth annual convention of Hadassah the Women's Zionist Organization of America, held in Cleveland, Ohio, in November, an appropriation of \$900,000 was made for medical work, including the initiation of a building fund for a new 250-bed tuberculosis hospital which the group hopes to erect soon in Palestine as the first step in its postwar health program for the Yishub. The new hospital will be an integral part of the Rothschild-Hadassah-University Hospital, which is the chief unit of the Hadassah Medical Center on Mt. Scopus, outside of Jerusalem.

# Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers.

## RECEIVED

**A Laboratory Manual of Physiological Chemistry.** By D. Wright Wilson. Fifth edition. Octavo of 269 pages. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$2.50.

**The Practice of Medicine.** By Brig. Gen. Jonathan Campbell Meakins, M.D., (MC), Royal Canadian Army. Fourth edition. Quarto of 1,444 pages, illustrated. St. Louis, C. V. Mosby Co., 1944. Cloth, \$10.

**Global Epidemiology. A Geography of Disease and Sanitation.** By James Stevens Simmons, M.D., Tom F. Whayne, M.D., Gaylord West Anderson, M.D., Harold MacLachlan Horack, M.D., and collaborators. Vol. I. Part One: India and the Far East. Part Two: The Pacific Area. Octavo of 504 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1944. Cloth, \$7.00.

**Diseases of the Digestive System.** Edited by Sidney A. Portis, M.D. Second edition. Octavo of 932 pages, illustrated. Philadelphia, Lea & Febiger, 1944. Cloth, \$11.

**The Radiology of Bones and Joints.** By James F. Brailsford, M.D. Third edition. Octavo of 440 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$12.

**Plaster of Paris Technic.** By Edwin O. Geckeler, M.D. Octavo of 220 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$3.00.

**Malaria: Its Diagnosis, Treatment and Prophylaxis.** By Col. William N. Bispham, M.D., U.S.A., Retired. Octavo of 197 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$3.50.

**The Blood Pressure and Its Disorders Including Angina Pectoris.** By John Plesch, M.D. Octavo of 149 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$4.50.

**The Urinary Tract. A Handbook of Roentgen Diagnosis.** By H. Dabney Kerr, M.D., and Carl

L. Gillies, M.D. Duodecimo of 320 pages, illustrated. Chicago, Year Book Publishers, Inc., 1944. Cloth, \$5.50.

**The Diseases of the Endocrine Glands.** By Hermann Zondek. Fourth (second English) edition. Translated by Carl Prausnitz Giles, M.D. Octavo of 496 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$11.

**Operations of General Surgery.** By Thomas G. Orr, M.D. Quarto of 723 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$10.

**Manual of Military Neuropsychiatry.** Edited by Harry C. Solomon, M.D., and Paul I. Yakovlev, M.D., with the collaboration of Lt. Col. Wilfred Bloomberg, (MC), AUS, *et al.* Duodecimo of 764 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$6.00.

**A Textbook of Pathology. Pathologic Anatomy in Its Relation to the Causes, Pathogenesis, and Clinical Manifestations of Disease.** By Robert Allan Moore. Octavo of 1,338 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$10.

**The Diagnosis and Treatment of Acute Medical Disorders.** By Francis D. Murphy, M.D. Octavo of 503 pages, illustrated. Philadelphia, F. A. Davis Co., 1944. Cloth, \$6.00.

**Gynecological and Obstetrical Urology.** By Houston S. Everett, M.D. Octavo of 517 pages, illustrated. Baltimore, Williams & Wilkins Co., 1944. Cloth, \$6.00.

**Surgery of the Hand.** By Sterling Bunnell, M.D. Quarto of 734 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1944. Cloth, \$12.

**Essentials of Pharmacology and Materia Medica for Nurses.** By Albert J. Gilbert, M.D., and Selma Moody, R.N. Second edition. Octavo of 290 pages, illustrated. St. Louis, C. V. Mosby Co., 1944. Cloth, \$2.50.

## REVIEWED

**Medical Parasitology and Zoology.** By Lt. Col. and Flight Surgeon Ralph Welty Nauss, MRC, USA. Octavo of 534 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$6.00.

In this volume of 534 pages the author has sought to present logically, simply, and concisely the salient things which the medical student and physician of today should know about medical parasitology. The text is written with the medical student in mind, and the approach is clinical rather than zoologic. The well-known standard works on medical parasitology are too detailed and extensive to be ideal textbooks for the brief courses on the subject offered by most medical schools, and it appears to this reviewer that the author has succeeded admirably in producing a shorter though adequate text appropriate for the usual medical school course. In addition to chapters on the pathogenic protozoa, hel-

minths, and arthropods of medical importance, there is included a section on poisonous reptiles and fishes. A good technical appendix is provided and there is an excellent glossary of terms peculiar to the subject, with their derivations, which should be particularly helpful to students who have trouble with nomenclature.

E. J. TIFFANY

**Strophanthin. Clinical and Experimental Experiences of the Past 25 Years.** By Bruno Kisch, M.D. Octavo of 158 pages, illustrated. New York, Brooklyn Medical Press, 1944. Cloth, \$4.00.

This book is an exhaustive review of the literature on strophanthin. Although much of the material is interesting and important, the value of the book is somewhat impaired by the controversial

[Continued on page 2756]

# CAMERON EQUIPMENT FOR YOU

## THE ELECTRO-DIAGNOSTOSET (The Outstanding Case of Good Practice)

TRIED AND PROVED BY MORE THAN 90,000 MEMBERS OF PROFESSIONS WHO USE AND RECOMMEND IT! MADE TO LAST AND SATISFY!

The Cameron Electro-Diagnostoset is a combination of electrically lighted instruments furnishing abundant light for every purpose, together with the latest mechanical improvements for control of the field under examination or operation and for use in every office or cavity of the body

## THE CAUTERODYNE (Radio-Frequency Scalpel, Cautery and Coagulator)

The CAUTERODYNE is a portable radio-frequency cautery-scalpel for all surgery such as appendectomies, cholecystectomies, herniotomies, prostatectomies, hysterectomies, gastrectomies, hemorrhoidectomies, and intestinal anastomoses, fistulae, and infected areas, especially those inaccessible with other methods. It is particularly indicated in carcinomatous conditions of the breast, cervix, bladder and tongue, and is ideal for surgical dissection in biopsies. This instrument is also used in es, epitheliomas, and other superficial neoplasms, and

CAUTERODYNE is clean, rapid, practically bloodless, and From \$125.00 up

## OPHTHALMOSCOPES Any Type . . . from \$18.50 to \$75.00

city current or lens, priced from \$18.50 to \$75.00. Lens changes in 1/2 minute. Ophthalmoscope, Day Light Ophthalmoscope, Red Free Ophthalmoscope, Pin-Point Ophthalmoscope and Retinoscope, and Bar Light Ophthalmoscope and Retinoscope.

The specialist finds these instruments of special value because of their simplicity and improved lighting system, and the general practitioner finds them peculiarly serviceable because of the use of a dark room or mydriatics is minimized in routine diagnosis. Both May and Loring Type instruments available.

## FLEXIBLE GASTROSCOPES & THE CAVICAMERA

The need of a dependable American source of supply and service for an instrument so necessary in combating gastrointestinal disturbances and cancer of the stomach is obvious. The Cameron Flexible Gastrosopes have an improved lens and optical system of 46 elements, which gives the maximum of magnification with a much sharper, clearer and better defined picture than heretofore obtainable. The Cavicamera takes pictures of the stomach lining in natural colors through the flexible gastroscope. Can also be used with cystoscopes, etc.

*Serving the Profession Since 1915 . . .*

[Continued from page 2754]

attitude of its author and by occasional obscurities in the text, due to unfortunate and inadequate choice of words.

For the present, however, it constitutes the only modern exhaustive treatment of the subject, and, as such, will be found useful by many.

ARTHUR SHAPIRO

**The American Illustrated Medical Dictionary. A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, etc.** By W. A. Newman Dorland, M.D., Lt. Col., MRC, USA. Twentieth edition, revised. Octavo of 1,668 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth. Plain, \$7.00. Thumb-indexed, \$7.50.

The many virtues of this dictionary, pointed out in the JOURNAL's review of the last edition, have been retained and amplified in the current edition. There has been a thorough revision, with no important omissions.

The illustrations are few and to the point. The tables are good and the method employed in indicating pronunciation is highly satisfactory. In short, we can continue to recommend the *American Illustrated Medical Dictionary* to student and practitioner.

MILTON PLOTZ

**Psychosomatic Diagnosis.** By Flanders Dunbar, M.D. Octavo of 741 pages. New York, Paul B. Hoeber, Inc., 1943. Cloth, \$7.50.

The old controversy as to the relationship between psyche and soma, the riddle as to whether the egg or the chicken is the dominant force, has been resuscitated in recent years and now has become a topic of much discussion. Psychosomatic medicine is the new tent for this all-inclusive and far-reaching controversial subject.

Dr. Dunbar's volume on psychosomatic diagnosis is an excellent and thorough treatise. Its appearance is timely and it should be read by all those who are interested in probing into some of these syndromes.

A. M. RABINER

**Physical Medicine in General Practice.** By William Bierman, M.D. Octavo of 654 pages, illustrated. New York, Paul B. Hoeber, Inc., 1944. Cloth, \$7.50.

This work is a valuable contribution to physical medicine. The author divides his subject-matter into twenty-three chapters. He individualizes each modality of physical therapy in a separate chapter, taking twelve chapters, or practically two thirds of the book. He then has a chapter on occupational therapy. The general conduct of treatment takes another chapter. The remainder of the book, or nine chapters, is devoted to systems and their diseases. The book is well written, very readable, and a useful addition to our literature.

JOHN J. HAUFF

**Aesculapius in Latin America.** By Aristides A. Moll. Octavo of 639 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$7.00.

This book is truly amazing. Its author, former editor of the Spanish edition of the *J.A.M.A.*, unfolds the giant panorama of Latin American medicine in those vast lands which begin at the Rio Grande and end at Cape Horn. The reader will find many great names, and will derive much inspiration from the public and professional achieve-

ments of our medical friends in Central and South America. Today their great hospitals and medical schools yield to none in this country.

An excellent index and many illustrations add to the interest of the book.

CHARLES A. GORDON

**Physiological Regulations.** By Edward F. Adolph. Quarto of 502 pages, illustrated with diagrams. Lancaster, Pa., Jaques Cattell Press, 1943. Cloth, \$7.50.

The author says: "This is a monograph recording an investigation in quantitative physiology." In it he records data and conclusions based on a large number of quantitative observations on the way in which the body of the human or experimental animal reacts to increased loads which tend to displace it from its usual equilibrium. Although the reasoning is detailed and some of the derived concepts rather abstract, the conclusions are summarized and stated in clear and understandable language.

The general implications of this work are sufficiently significant to make it one of the classics of modern physiology.

ARTHUR SHAPIRO

**What Is Hypnosis?** By Andrew Salter. Duodecimo of 88 pages. New York, Richard R. Smith, 1944. Cloth, \$2.00.

This little book is an elementary presentation of the subject of hypnosis. There is a chapter devoted to the three different technics, which should be of some help to the novice. This book should interest those who wish to acquire an elementary knowledge of this subject.

IRVING J. SANDS

**Hydronephrosis and Pyelitis (Pyelonephritis) of Pregnancy.** By H. E. Robertson, M.D. Duodecimo of 332 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$4.50.

As an extraordinarily able and interesting recapitulation of all our knowledge of a very important subject, this little book from the Mayo Clinic should be appreciated by obstetricians and urologists. Actually it is a historical survey of the facts and theories concerned with dilatation and infection of the urinary tract in pregnancy.

The author offers his review with hesitancy, yet his method might well be imitated in a host of other conditions. This work is highly recommended.

CHARLES A. GORDON

**The Art and Science of Nutrition. A Textbook on the Theory and Application of Nutrition.** By Estelle E. Hawley and Grace Carden. Second edition. Octavo of 668 pages, illustrated. St. Louis, C. V. Mosby Co., 1944. Cloth, \$3.75.

Recognizing the fact that the busy physician usually has time to do little more than indicate the type of dietary treatment necessary for a patient, the authors of this book plan to give nurses the background and information necessary to fill in the outlined treatment. It is a good book. Given the information here, a nurse should be able to prepare meals that will both appeal to and meet the needs of the patient.

The sections on diet in special conditions and on diet therapy develop logically and clearly from the early chapters on normal nutrition. The information on the choice, preparation, and serving of foods is very adequate.

[Continued on page 2758]

# For LOCAL ANESTHESIA PROCAINE HYDROCHLORIDE

*Brewer*

Current literature continues to report on the use of Procaine Hydrochloride as a local anesthetic.

In the removal of moles, ordinary seborrheica and senile keratoses from the body, the area is first anesthetized with procaine hydrochloride (A. Benson Cannon, N. Y. S. J. M., Vol. 40, No. 21, p. 1569).

As less toxic than most cocaine substitutes it is especially safe for the production of spinal anesthesia. Its continued use for infiltration anesthesia, conduction anesthesia, for topical use in ophthalmology, in rhino-laryngology and for urethral anesthesia finds it still indispensable to the doctor.

Supplied in 2 per cent solution  
in ampules of 2 cc. and 30 cc.

**BREWER & COMPANY, INC.** Worcester

The style is interesting, and the illustrations and color plates are well chosen and liberal. This revised edition, brought up to date on the newest findings and recommendations in nutrition, is recommended as serving its declared purpose most admirably.

ETHEL PLOTZ BERMAN

**Fundamentals of Internal Medicine.** By Wallace Yater, M.D. Second edition. Octavo of 1204 pages, illustrated. New York, D. Appleton Century Co., Inc., 1944. Cloth, \$10.

The second edition of Yater's *Fundamentals of Internal Medicine* has been thoroughly revised and has all of the virtues of the first edition and a number of new ones. As far as it goes, the book is reliable, up-to-date, and extremely intelligently organized.

Yater is the best review of internal medicine which I have seen, but there is considerable doubt in my mind that it can be safely used as a textbook in internal medicine. It has the great disadvantage that, no matter how competently written and organized, it accustoms the beginner to study from an outline. It can, therefore, be recommended for review purposes but not as a primary textbook.

Three new sections have been added: Symptomatic and Purported Treatment, Clinical Values and Useful Tables, and The Physician Himself, which greatly enhances the value of this volume. The last of the chapters is especially commendable. One can only regret, however, that no mention was made in this chapter of Cathell's book on *The Physician Himself* which influenced so many American doctors.

MILTON PLOTZ

**Urological Surgery.** By Austin Ingram Dodson, M.D., and others. Octavo of 768 pages, illustrated. St. Louis, C. V. Mosby Co., 1944. Cloth, \$10.

The book is a clear, concise, well-written, modern contribution to the field of urologic surgery. The

work is basically surgical therapy but embraces the pathologic and various diagnostic procedures as a necessary prerequisite. It is fully and vividly illustrated by Helen Lorraine. A few chapters are written by collaborators representative of their respective fields. The author has followed the more modern custom of listing references to the literature at the end of each chapter. The chief features of the book are those of surgical technic. These should prove useful and valuable as a ready reference to all those attempting to perform major operations on any part of the urogenital tract.

AUGUSTUS HARRIS

**Collected Papers of the Mayo Clinic and the Mayo Foundation.** Edited by Richard M. Hewitt, M.D., and others. Vol. 35, 1943. Octavo of 875 pages, illustrated. Philadelphia, W. B. Saunders Co., 1944. Cloth, \$11.

In spite of the war, the most recent Mayo volume maintains its high degree of excellence. It lives up to its aim to be of value to the general practitioner, the general surgeon, and the diagnostician. The reviewer was especially impressed with papers devoted to the study of esophageal pain, carcinoma of the gallbladder, metastatic carcinoid tumors of the ileum, chemotherapy in digestive disorders, the management of ulcerative colitis, the sedimentation rate in benign hypertrophy and carcinoma of the prostate gland, ovarian tumors, abnormal uterine bleeding, hyperparathyroidism, alopecia in Addison's disease, coronary disease, pathology in hypertension, orthostatic hypotension, venous thrombosis in obscure visceral carcinoma, lame backs, benign and malignant tumors of the bone, fibrositis, carcinoma of the lung, bronchiectasis, post-operative subarachnoid hemorrhage, sleep paralysis, and roentgenologic diagnosis of gastric cancer. All in all, the book deserves to be read from cover to cover.

M. A. RABINOWITZ

**SOS** in **HYPERTENSION**  
Answer it with **HEPVISC**

High blood pressure brought down to safer levels by gradual, prolonged action of HEPVISC. Also relieves headaches and dizziness.

DOSE: 1-2 tablets t.i.d., after meals.  
Sample and formula on request.

**RICCI**

By JAMES V. RICCI, A. B., M. D.

Clinical Professor of Gynaecology and Obstetrics, *New York Medical College, Director of Gynaecology, City Hospital, New York, etc.*

# The Genealogy of Gynaecology

*Review in New England Medical Journal*

54 illus.

578 Pages

\$8.50

"This is an authoritative, scholarly and well-documented history of gynaecology from its remotest archaic beginnings through the Assyrian, Babylonian, Egyptian and Hindu epochs, the classic Graeco-Roman age, the Talmudic, Byzantine and Arabic eras and the Middle Ages and Renaissance to the end of the eighteenth century. From all these epochs there is an abundant bibliography and the reproduction of fifty-three well-selected illustrations, chiefly of gynaecologic instruments and of developing anatomical concepts. In his preface, as in his gracious dedication to the Harvard Medical School, the author freely acknowledges his indebtedness to previous writers but modestly underestimates the wide-ranging and painstaking research that the accumulation of his material must have required. His work is a priceless gift to the profession, and one waits with eager anticipation for the subsequent volume, promised in the introduction by Dr. Schumann, of Philadelphia, covering the period of the nineteenth century."

**THE BLAKISTON COMPANY** PHILADELPHIA 5, PA.**DIRECTORY OF TUBERCULOSIS CLINICS IS ISSUED**

York Tuberculosis and Health Association and Medical Director of Triboro Hospital in Queens

According to Dr. [Name], the Association, the information on the [Name]

district clinics and the seventeen nondistrict clinics which serve the five boroughs of New York City. Of the forty-one tuberculosis clinics, nineteen are located in Manhattan, six in the Bronx, eight in Brooklyn, six in Queens, and two in Richmond. It includes also maps showing the boundaries for the tuberculosis district clinics and lists the branch offices of the Department of Health, as well as District Health Centers and tuberculosis admission bureaus for all boroughs.

Time has put most of these  
clocks out of running

Watchmaker in 1820

## But time has added to Johnnie Walker's popularity

Johnnie Walker still  
sets the pace among  
fine scotch whiskies.  
You get an extra margin  
of mellowness  
backed up by a fla-  
vour that's in a class  
by itself.

Popular Johnnie  
Walker can't be every-  
where all the time these  
days. If occasionally  
he is "out" when you  
call... call again.

BORN 1820

Still going strong
